Critical Care 2013, 17(Suppl 4):P1; doi:10.1186/cc12902

Background: Reliable surveillance methods are indispensable for benchmarking of healthcare-associated infection rates. The National Healthcare Safety Network (NHSN) recently introduced surveillance of ventilator-associated events (VAE), including ventilator-associated conditions (VAC) [1]. This new algorithm is amenable to automated implementation and strives for more consistent interpretation. We assess the feasibility and reliability of automated implementation.

Materials and methods: Retrospective analysis of an ICU cohort with prospective assessment of ventilator-associated pneumonia (VAP) in two academic medical centers (January 2011 to June 2012). Two minor modifications were developed to improve stability and comparability with manual surveillance (10th percentile and intermittent ventilation). Concordance was assessed between the algorithms and prospective surveillance. Attributable mortality of VAC was estimated by multivariable competing-risk survival analysis.

Results: Two thousand and eighty patients contributed 2,296 episodes of mechanical ventilation (MV). VAC incidence was 10.0/1,000 MV days. Prospective surveillance identified 8 VAP cases/1,000 MV days. The original VAC algorithm detected 32% (38/115) of patients affected by VAP; positive predictive value was 25% (38/152). Using the 10th percentile identified the same number of VAC cases, but only 116 were identical. VAC incidence was 24.9/1,000 MV days with the intermittent ventilation modification. Concordance between the original algorithm and the modified version was suboptimal. Estimates of attributable mortality varied by implementation: original VAC subdistribution hazard ratio (sdHR) = 4.33, 10th percentile sdHR = 6.26 and intermittent ventilation sdHR = 2.40.

Conclusions: Concordance between manual VAP surveillance and the VAC algorithm was poor. Although electronic implementation of the VAE algorithm was feasible, small variations considerably altered the events detected and their effect on mortality. Using the current specifications, comparability across institutions using different electronic or manual implementations remains questionable.

Acute kidney injury decreases long-term survival over a 10-year observation period
Adam Linder1*, Adeera Levin2, Keith Walley1, James A Russell1, John H Boyd1
1Centre for Heart Lung Innovation, Division of Critical Care Medicine, St Paul’s Hospital, University of British Columbia, Vancouver, BC, Canada; 2Division of Nephrology, St Paul’s Hospital, University of British Columbia, Vancouver, BC, Canada
Critical Care 2013, 17(Suppl 4):P2; doi:10.1186/cc12903

Background: We hypothesized that single episode of acute kidney injury (AKI) reduces long-term survival compared with no acute kidney injury (No AKI) following recovery from critical illness.

Materials and methods: A prospective cohort of 2,010 patients admitted to the ICU between 2000 and 2009 at a provincial referral hospital was followed to determine whether AKI influences long-term survival.

Results: Of the 1,844 eligible patients, 18.4% had AKI stage 1, 12.1% had stage 2, 26.5% had stage 3, and 43.0% had No AKI, using the K/DOQI classification. The mean and median follow-up time was 8.1 and 8.7 years. The 28-day, 1-year, 5-year and 10-year survival rates were 59.6%, 44.9%, 37.4%, and 33.4%; in patients with any AKI (stage 1, stage 2, stage 3), which was significantly worse compared with the critically ill patients without AKI at any time (P < 0.01). The adjusted 10-year mortality risk associated with AKI was 1.44 (95% CI = 1.2 to 1.7) among 28-day survivors. Patients who had mild AKI (stage 1) had significantly worse survival at 28 days, 1 year, 3 years, 5 years and 10 years compared with No AKI (P < 0.01) (Figure 1A). Patients with sepsis and AKI who survived 28 days had significantly poorer 5-year and 10-year survival compared with nonseptic AKI (P < 0.01) (Figure 1B).

Conclusions: Patients with one episode of mild (stage 1) AKI have significantly lower survival rates over 10 years than critically ill patients without AKI. The causes and mechanisms of this association warrant further careful study. Close medical follow-up of these patients may be warranted and mechanistic research required understanding how AKI influences distant events.

P3
Heparin-binding protein improves prediction of severe sepsis in the emergency department
Adam Linder1*, Ryan Arnold2, Marco Zindovic1, Igor Zindovic1, Anna Lange-Jendeberg1, Magnus Paulsson1, Patrik Nyberg1, Bertil Christensson1, Per Åkesson1
1Skåne University Hospital, Lund, Sweden; 2Cooper University Hospital, Camden, NJ, USA; 3Orebro University Hospital, Orebro, Sweden

Background: Heparin-binding protein (HBP) has been shown to be a reliable diagnostic marker for severe sepsis in emergency medicine. This novel biomarker has recently been shown to improve performance of the Sequential organ failure assessment (SOFA) model for the prediction of disease severity in sepsis. The aim of this study was to evaluate whether addition of HBP improves prediction of severe sepsis in an emergency medicine setting.

Methods: In this prospective cohort study, 884 patients presenting to the emergency department were included. SOFA and HBP were measured on admission. A nested case-control study was performed to identify risk factors for severe sepsis. Receiver operating characteristic (ROC) curve analysis was used to assess the performance of each biomarker.

Results: Of the 884 patients, 26 patients were identified as having severe sepsis. The addition of HBP to the SOFA model improved the area under the ROC curve from 0.84 to 0.87 (P < 0.01). Multivariate analysis identified HBP as an independent predictor of severe sepsis.

Conclusions: The addition of HBP to the SOFA model improves prediction of severe sepsis in the emergency department.
Background: The early identification of risk of developing severe sepsis in patients with suspected infection remains a difficult challenge. We hypothesized that an elevated plasma level of heparin-binding protein (HBP), a neutrophil-secreted mediator of vascular leakage, would be a predictor of delayed clinical deterioration and progressive organ dysfunction in emergency department (ED) sepsis patients.

Materials and methods: A prospective, multicenter study in Sweden and the US was conducted of 763 patients presenting to an ED with a suspected infection and signs of systemic inflammation. Based on recorded clinical and laboratory parameters and final diagnoses, patients were classified into various groups depending on the severity of the infection and inflammatory response. Plasma levels of HBP were measured and compared with levels of other standard sepsis biomarkers including procalcitonin, lactate, WBC, and C-reactive protein.

Results: The final diagnoses were severe sepsis with organ failure in 338 patients, nonsevere sepsis without organ failure in 340 patients, and no infection in 85 patients. One-hundred and forty-three patients (19%) presented without signs of severe sepsis, but developed delayed circulatory failure and/or organ dysfunction within 72 hours of enrolment. In this patient group, an elevated HBP level could predict the delayed

Figure 1(abstract P2) A: Bar chart showing that patients with AKI of any stage had significantly poorer mean survival rates compared to control patients with no AKI, at 28-days, 90-days, 1-year, 3-years, 5-years and 10-years after enrolment. B: Unadjusted Kaplan-Meier curves showing the 10-year survival from ICU admission for patients classified as having any stage of AKI according to the KDIGO classification using serum creatinine. Time is calculated from 28 days after admission (28-day survivors). Mantel-Cox Log Rank showed a significant difference in mortality between the two curves with or without AKI.
development of severe sepsis with an AUC value of 0.86. Elevated HBP levels (>30 ng/ml) were found in 80% of the patients and elevated procalcitonin levels (>0.5 ng/ml) were detected in 59%, 10.5 hours (median) before developing severe sepsis.

Conclusions: Detection of elevated plasma-HBP levels may help to provide an early risk-stratification of patients with suspected infections in the ED. An elevated HBP level was independently able to predict delayed clinical deterioration to overt shock or severe sepsis with organ failure.

Impact of the Surviving Sepsis Campaign clinical guideline of in sepsis mortality in a public health institution in Brazil
Suellen C de Aguiar, Guilherme F Garcia, Daniela N Ferreira, Francisco C de Souza, Valda MF Mendonça, Vanuza F Ribeiro, Lívia M Ferreira, Flávio D Capanema, Luana C de Carvalho, Marina F de Gomes
Comissão Central de Protocolos Clínicos, Fundação Hospitalar do Estado de Minas Gerais, Belo Horizonte, MG, Brazil

Critical Care 2013, 17(Suppl 4):P4; doi:10.1186/cc12905

Background: Sepsis is the principal cause of mortality in intensive therapy units (ITU’s) around the world [1]. Several international organizations created in 2002 the Surviving Sepsis Campaign (SSC), targeting the reduction of sepsis mortality in 25% during 5 years [2]. The Fundação Hospitalar do Estado de Minas Gerais (FHEMIG), Brazil, was incorporated in this campaign with eight hospitals (four general hospitals, one trauma hospital, one oncologic center, one infectious diseases center, one maternity hospital). The aim of this study is to evaluate the impact of using the SSC sepsis protocol in severe sepsis and sepsis shock lethality in the FHEMIG net hospitals.

Materials and methods: This is a retrospective cohort study based on eight ITU public hospitals. The inclusion criteria were patients with severe sepsis and sepsis shock according to the SSC protocol, from January 2010 to December 2012, aged older than 18 years, which had a final outcome of hospital discharge or death. The sepsis lethality was compared annually from 2010 to 2012. Since 2010, the implementation of educative and managerial measures was based on the SSC guidelines: auditing of medical charts; education in sepsis care; issue of booklet and posters about sepsis; inclusion of sepsis information in the medical residence program; and collaboration of hospital directors in monitoring and giving information of the sepsis guideline. The study was approved by the Institutional Ethical and Research Committee. Data were collected and analyzed on EPIINFO software, using ANOVA test for comparisons with precision of 95%.

Results: In the period of 3 years, 1,698 severe sepsis and sepsis shock patients were registered and 1,152 (67.84%) died. We verified a reduction of 12% (P = 0.0073) on lethality global. Hospitals 2 and 6 had a significant reduction on lethality, of 35% (P < 0.0001) and 17% (P = 0.0073) respectively (Table 1).

Conclusions: The sepsis lethality is still high in this institution (64.1%), compared with the Public Hospitals in Brazil (59.6%) and the world rate (30.8%) [3]. After the adoption of managerial measures based on the SSC protocol, there was a significantly reduction in lethality, but only one hospital reached the target reduction of 25% on lethality. This heterogeneity could be explained by different engagements of the professional board and director and different patient’s profiles. The sepsis mortality is a major challenge in the world [4], and application of the SSC protocol led to a significant reduction in sepsis lethality.

Acknowledgements: The authors would like to acknowledge the assistance of the staff and local protocol team of the participant hospitals: Hospital João XXIII, Hospital Alberti Cavalcanti, Hospital Geral de Barbacena, Hospital Júlia Kubitschek, Hospital Eduardo de Menezes, Maternidade Odete Valadares, Hospital Regional João Penido and Hospital Regional Antônio Dias.

Passive immunotherapy of extended peritonitis as abdominal sepsis prevention
Olexandr Butyrskyy*, Viktor Starosiek
Department of Surgical Diseases, Crimean State Medical University, Simferopol, Ukraine

Critical Care 2013, 17(Suppl 4):P5; doi:10.1186/cc12906

Background: The outcome of extended peritonitis is determined by many factors including antimicrobial defense. Microbial invasion, surgery, and intensive therapy cause secondary immunity deficiency associated with septice complication incidence and post-surgery lethality. The great importance in initialization and supporting these processes belongs to Escherichia coli endotoxin that participates in digestive tract immunity and general immunoresistance.

*\( P < 0.001 \).

Materials and methods: Thirty-two patients ages 15 to 86 (male:female = 24:8) treated for extended peritonitis were investigated. Blood was sampled after admission and in 5 days to determine anti-lipopolysaccharide antibodies of different classes (anti-LPS-IgA, anti-LPS-IgG, anti-LPS-IgM, respectively) by hard-phase immunoenzyme analysis. The control group included 10 healthy donors (opt.un.); anti-LPS-IgA - 0.348 ± 0.053, anti-LPS-IgM - 0.162 ± 0.01, anti-LPS-IgG - 0.333 ± 0.051.

Results: Patients with high levels of anti-endotoxin immunity were 15.6% (n = 5) (Table 1); after surgery they had rapid recovery, normalization of peristalsis and laboratory parameters by the 5th day. Patients of low immunity level were 84.4% (n = 27); they had a long complicated recovery period. In group I for standard treatment within 5 days one noticed evident shifts of all parameters that witnesses its sufficiency. In group II the parameters are not decreased evidently, which testifies to necessity of additional immunocorrection. Low immunity level patients were introduced to 3 ml sandoglobulin H on the 5th day after surgery that was associated with a sharp increase of anti-LPS antibody titer (Table 2). Growth of anti-LPS antibody titer was associated with positive dynamics of inflammation progress, and prevents abdominal sepsis.

Conclusions: The majority of peritonitis patients have decreased competent anti-LPS antibodies, which determines the severity of the post-surgery period. Low immunity level patients need passive nonspecific immunotherapy that stimulates protective functions, blocks mechanisms of inflammation progress, and prevents abdominal sepsis.

Efficacy of specific immunotherapy of abdominal sepsis

Olexandr Butyrs’kyi1, Iryna Butyrs’kyi2
1Department of Surgical Diseases, Crimean State Medical University, Simferopol, Ukraine; 2Department of Hygiene, Crimean State Medical University, Simferopol, Ukraine

Critical Care 2013, 17(Suppl 4):P6; doi:10.1186/cc12907

Background: According to the 2004 WHO Annual Report, abdominal sepsis (AS) is one of the most dangerous diseases of the 21st century. But the issue of its treatment including immunotherapy is very far from being completely solved. Our aim was the demonstration of specific immunotherapy efficacy in AS.

Materials and methods: We investigated activity of immunogenesis (production of specific antibodies) in AS in 50 patients under impact of hyperimmune plasma infusion obtained from the donors who recently

dured acute inflammatory abdominal diseases. The control group was made up of 10 healthy people.

Results: Our investigations demonstrated that the donors’ titer of specific antibodies is evidently more according to indexes of anti-Escherichia coli, anti-Pseudomonas aeruginosa, anti-Staphylococcus aureus, anti-bacteroids, anti-peptococci immunity. Introducing hyperimmune plasma obtained from such donors evidently increases specific antibody titer in AS patients (Table 1).

Results: Our results demonstrated that the titer of specific antibodies to AS main agents in the dead patients was evidently lower in comparison with the control group and in recovered people. This trend is observed 7 to 10 days after surgery. For example, at admission the titer of anti-S. aureus antibodies in dead patients was 11% lower in comparison with the control group, and the titer of anti-E. coli antibodies 19% lower in comparison with control group and 32% lower in comparison with recovered patients; 7 to 10 days after surgery in dead patients in comparison with recovered patients, the titer of anti-S. aureus antibodies was lower by 22%, and the titer of anti-E. coli antibodies by 47%.

Conclusions: Introducing hyperimmune plasma (specific immunotherapy) increases titer of specific antibodies, and increased concentration of specific antibodies improves forecast of survival in AS.

Characteristics and outcomes of patients with culture negative septic shock compared with patients with culture positive septic shock: a retrospective cohort study

Shravan Kethireddy1, Amanda Bengier2, H Lester Kirchner3, R Bruce Light3, Yazdan Mirzanejad4, Dennis Maki5, Yaseen Arabi6, Steven Lapinsky7, David Simon8, Aseem Kumar9, Joseph E Parrillo10, Anand Kumar3, the Cooperative Antimicrobial Therapy of Septic Shock (CATSS) Database Group

Background: Previous studies have identified that nearly 30% of patients with severe sepsis and septic shock lack a definitive microbial etiology. The characteristics and outcomes of culture negative septic shock are not well defined despite large epidemiologic studies on septic shock.

Materials and methods: Retrospective nested cohort study of 2,651 patients with culture-negative septic shock and 6,019 culture-positive septic shock patients derived from a trinational, 8,760-patient database of patients with septic shock between 1989 and 2008.

Results: In total, 30.6% of cases of septic shock cases were identified as culture-negative within the database. Patients with culture-negative septic shock (CNSS) experienced similar ICU mortality as did those with culture-positive septic shock (CPSS) (41.7% vs. 40.5%, P = 0.289) (Tables 1 and 2).

Similar to our previous findings, we identified by the second hour after onset of persistent/recurrent hypotension that the in-hospital mortality rate was significantly increased relative to receiving therapy within the first hour (odds ratio, 1.62; 95% CI, 1.21 to 2.15; P = 0.001) in the CPSS group. Following increasing delays in the administration of appropriate antimicrobial therapy over the first 6 hours after the onset of hypotension, patients in both groups experienced nearly congruent, significant increases in hospital mortality; at 6 hours the CNSS group (odds ratio, 2.87; 95% CI,

Conclusions: Patients with CNSS behave similarly to CPSS patients in nearly all respects. As with bacterial septic shock, early appropriate antimicrobial therapy appears to improve mortality. Earlier recognition of infection is the most obvious effective strategy to improve hospital survival. Optimal duration of therapy is not well defined among patients with CNSS. In addition to early, appropriate antimicrobial therapy, use of de-escalation strategies such as serial procalcitonin levels may be useful to determine the length of empiric broad-spectrum antimicrobial use in this population.

SRT2379, a small-molecule SIRT1 activator, fails to reduce cytokine release in a human endotoxemia model
Maryse A Wiewel1*, Anne Jan van der Meer1, Jonathan Haddad2, Eric W Jacobson2, George P Vlasuk2, Tom van der Poll1

Critical Care 2013, Volume 17 Suppl 4
http://ccforum.com/supplements/17/S4
Page 6 of 59

Background: SRT2379 is a selective small-molecule activator of the NAD+-dependent deacetylase, Siruin 1 (SIRT1), which has broad anti-inflammatory effects in cell cultures and rodents. The aim of the current
study (EUDRACT # 2011-002266-20) was to determine the effect of SRT2379 on the inflammatory responses in normal healthy male subjects after exposure to LPS.

Materials and methods: This single-blind, placebo-controlled study consisted of four treatment arms (n = 8 per arm): (1) oral SRT2379 50 mg; (2) oral SRT2379 250 mg; (3) oral SRT2379 1000 mg; and (4) placebo. All subjects received a single dose of study drug on day 1 followed by intravenous LPS 4 hours later. Laboratory parameters of inflammation along with assessment of clinical signs, safety assessments, and pharmacokinetic measurements were recorded at baseline and after LPS administration.

Results: SRT2379 was well tolerated. Adverse events were similar across all treatment groups and were predominantly as expected with LPS administration. Pharmacokinetic exposures increased in a dose-dependent manner. SRT2379 did not significantly impact cytokine release as compared with placebo. TNFα (183.52, 177.57, 123.64 vs. 195.30 pg/ml for groups 1, 2, vs. group 4, respectively, P > 0.05), IL-6 (195.25, 237.51, 180.26 vs. 250.08 pg/ml, respectively, P > 0.05), IL-17 (3.88, 2.59, 6.42 vs. 8.09 pg/ml, respectively, P > 0.05), IL-8 (12.16, 10.25, 110.56 vs. 108.77 pg/ml, respectively, P > 0.05), and IL-10 (12.61, 13.03, 40.40 vs. 11.90 pg/ml, respectively, P > 0.05). SRT2379 also had no impact on vital signs, leukocyte counts, or coagulation activation markers compared with placebo.

Conclusions: Although SRT2379 suppresses inflammatory markers in preclinical experiments, we were unable to demonstrate a similar impact in this human model of endotoxemia. This may be due to potency or exposure issues, with the compound. SRT2379 terminated for further clinical development. More promising candidates are being identified for future clinical exploration.

Bacteriological profile and antimicrobial sensitivity pattern of blood culture isolates among septicaemia-suspected children at Tikur Anbessa Specialized Hospital and Yekatit 12 Hospital, Addis Ababa, Ethiopia

Adugna Negussie1,2, Gebra Muleygita1, Ahmed Bedru3, Ibrahim Ali1,2, Damte Shimesle4, Tsehaynesh Lema1, Abraham Asefa1

1Department of Medical Laboratory Science, College of Health Science, Addis Ababa University, Ethiopia; 2Department of Public Health Officer, Jigjiga University, Jigjiga, Ethiopia; 3Armauer Hansen Research Institute, Addis Ababa, Ethiopia; 4Tikur Anbessa Specialized Hospital, Department of Pediatrics, Addis Ababa, Ethiopia

Critical Care 2013, 17(Suppl 4):P11; doi:10.1186/cc12911

Background: Septicemia is a systemic disease caused by the spread of microorganisms and their toxins in the blood. These bloodstream infections are a major cause of morbidity and mortality in children in developing countries [1-4]. It has been confirmed by culture that is associated with clinical manifestation and systemic response [5-7]. It is crucial to continuously monitor any change in the local patterns of infection and susceptibility to various antibiotics. The aim of this study was to determine the bacteriological profile and antimicrobial sensitivity patterns among children suspected of having septicemia.

Materials and methods: A cross-sectional study involved about 201 pediatric patients (<12 years) was conducted from October 2011 to February 2012 at Tikur Anbessa Specialized Hospital and Yekatit 12 Hospital’s pediatric units after the proposal of this study was approved by National Ethics Review Committee. Standard procedure was followed for blood sample collection. Samples were incubated in the BACTEC 9050 System, followed by isolate identifications based on standard microbiological procedures and testing for their susceptibility to antimicrobial agents using the disc diffusion method. Data were analyzed using the SPSS version 19 software package.

Results: Out of 201 study subjects, 110 (54.7%) were male. The majority (147, 73.1%) of them were neonates (<28 days). The mean length of hospitalization was 11.24 days. Out of the 201 tested blood samples, blood cultures were positive in 56 (27.9%) cases (Figure 1). Gram-negative and Gram-positive bacteria constituted 51.8% and 46.4%, respectively. The most frequent pathogen found was Staphylococcus aureus (23.2%), followed by Serratia marcescens (21.4%), CoNS (19.6%), Klebsiella spp. (16%), Salmonella spp. (5.4%) and Enterobacter cloacae (3.6%) (Figure 2). The majority of bacterial isolates showed high resistance to ampicillin, penicillin, co-trimoxazole, gentamicin and tetracycline. Ciprofloxacin and nalidixic acid were the most effective antimicrobial agents for Gram-negative bacteria, while vancomycin and clindamycin for Gram-positive bacteria (Table 1). Deaths occurred in 25 (12.4%) children, out of which 13 (23.2%) had bacteremia.

Conclusions: The present study revealed that both Gram-positive and Gram-negative bacteria were responsible for bloodstream infections and the majority of the isolates were multidrug resistant. S. aureus and S. marcescens were the most common isolated bacteria from blood cultures. The alarmingly higher percentages of multidrug-resistant isolates urge us to take infection prevention measures and to conduct other large studies for appropriate empiric antibiotic choice.

Pentoxifylline therapy among preterm neonates <1,500 g in reducing mortality from neonatal sepsis: a double-blind, randomized placebo-controlled trial

Jessamine C Sareno*, Jacinto Blas V Mantaring
Department of Pediatrics, Section of Newborn Medicine, Philippine General Hospital, Metro Manila, Philippines

Critical Care 2013, 17(Suppl 4):P14; doi:10.1186/cc12914

Background: Pentoxifylline, a xanthine derivative, has raised new interest in neonatal research due to its immunomodulatory functions and its potential role in reducing mortality from sepsis. Two small studies on a per-protocol analysis have shown promising results. This larger trial on an intention-to-treat basis will determine whether the use of pentoxifylline as an adjunctive therapy for sepsis in preterm neonates (≤36 weeks) weighing <1,500 g will truly result in a reduction in the all-cause mortality.

Materials and methods: Preterm infants ≤1,500 g with suspected infection admitted to the NICU of a large tertiary, training, government hospital were eligible for inclusion in the study. After informed consent,
they were randomized to receive either pentoxifylline at a dose of 6 mg/kg/hour or placebo. Patients with major congenital malformations, congenital infections and severe hemorrage were excluded from the study. Pentoxifylline was administered as a 6 ml infusion for 6 hours for 6 days. The control group received normal saline in the same manner as the pentoxifylline infusion. Patients, parents and physicians (outcome assessors) were blinded to the treatment assignments. The primary outcome was analyzed on an intention to treat basis. The primary outcome measured in the study is the occurrence of all-cause mortality between the two groups. Secondary outcomes measured include mortality from sepsis, adverse drug reactions and length of hospital stay.

Results: A total of 312 neonates are included in this interim analysis: 156 in the pentoxifylline group and 156 in the control group. Baseline characteristics were comparable between the two groups. In this analysis, there is no difference in the occurrence of death among patients in the pentoxifylline group versus the placebo group (RR: 1.08 (0.83, 1.41)). There is no statistical difference in the risk of death from septic shock (RR: 1.03 (0.67, 1.59), P = 1.0). There was also no significant difference in the length of hospital stay in the two groups (36 days in treatment group vs. 35 days in control group, P = 0.910). No significant adverse drug reactions were noted with pentoxifylline use.

Conclusions: Pentoxifylline as an adjunct therapy for sepsis did not show a decrease in the all-cause mortality. There is also no difference in the occurrence of death from sepsis and length of hospital stay. No adverse drug reactions were noted with pentoxifylline.

Acknowledgements: The authors thank the neonatology fellows of the Philippine General Hospital and Ms Carmi Pitajen, RN, research assistant.

Page 10 of 59

Background: Sepsis is a serious clinical condition with a considerable morbidity and mortality. Procalcitonin (PCT) is a good biomarker for early diagnosis and infection monitoring. A semi-quantitative PCT assay can be performed at the bedside and has good diagnostic value [1,2]. The present study aimed to investigate the effect of a semi-quantitative PCT test on the empirical antibiotic initiation time, the appropriateness of empirical antibiotics and mortality in septic patients.

Materials and methods: The study design was a randomized diagnostic trial, which was also a pragmatic trial. Septic patients more than 18 years old with and without signs of organ hypoperfusion or dysfunction who were admitted to Cipto Mangunkusumo Hospital emergency department in the internal medicine unit were eligible. Subjects were randomly assigned to either a semi-quantitative PCT-examined group (study group) or a control group. Semi-quantitative PCT test results will be informed to the physicians taking care of the patients. The primary outcome was 14-day mortality. Secondary outcomes were the time of initiation and appropriateness of empirical antibiotics between the two groups. Subjects were the time of initiation and appropriateness of empirical antibiotics between the two groups.

Results: Two hundred and five patients met the inclusion criteria. Ninety-five of 100 subjects from the study group and 102 of 105 subjects from the control group were included in the analysis (Figure 1). Both groups have equal baseline characteristics (Table 1). The mortality risk was lower in the study group (RR 0.53; 95% CI 0.36 to 0.77). The study group had greater probability to have a first dose of empirical antibiotic in less than 6 hours compared with the control group (RR 2.48; 95% CI 1.88 to 3.26). No effect was seen in appropriateness of empirical antibiotics between groups (RR 0.99; 95% CI 0.92 to 1.08) (Table 2).

Conclusions: Semi-quantitative PCT examination affects the empirical antibiotic initiation time and mortality in septic patients, but not the appropriateness of empirical antibiotics.

Due to hyperinfection. Human strongyloidiasis is a neglected tropical disease of major worldwide distribution, affecting millions of people. Despite of the fact that infection with Strongyloides stercoralis is usually self-limited and with low morbidity in immunocompetent individuals, it may become lethal in cases of immunosuppression, such as AIDS, corticosteroid treatment and transplantation. Our aim in this work was to investigate the presence of S. stercoralis antigens and anti-parasitic IgG in sepsis patients in a highly endemic area of strongyloidiasis.

Materials and methods: Serum samples from 27 individuals with strongyloidiasis and 27 healthy subjects were used as positive and negative controls, respectively, according to their parasitological analyses. Additionally, 27 sepsis patients were also investigated. We have used ELISA tests to detect S. stercoralis antigens and IgG ant-S. stercoralis in all three groups. The cutoff value was determined by the ROC curves obtained by Prism 5.0 software.

Results: IgG anti-S. stercoralis was detected in six patients; five under septic shock and one with sepsis. Among them, four were positive for the parasite antigen-antibody immune complex; three under septic shock and one with sepsis, demonstrating that 15% of sepsis patients were infected by the parasite, which may have significantly contributed with the hyperinfection presented by septic-shock patients (10%).

Conclusions: There are only two reports of an association between S. stercoralis infection and immunosuppression, which led to lethal sepsis cases. However, our preliminary analysis through antigen-antibody
immune complex demonstrated that this parasitic infection might be more common in sepsis than expected. The correct diagnosis of the causal infection in sepsis may support the correct therapeutic choice, which is fundamental to avoid the continuous spread of specific pathogen/parasite triggers that will eventually lead to hyperinfection, and consequently to severe sepsis.

Acknowledgements: The authors would like to thank the patients and their families for the direct collaboration in this work, the medical staff from the ICU of the university hospital for providing the biological samples and the clinical parameters, and financial support by CNPq, CAPES, and FAPEMIG.

Procalcitonin, presepsin, pro-adrenomedullin, fibrin degradation products, and lactate in early diagnosis and prognosis of septic patients newly admitted to the intermediate care unit from the emergency department

Filippo Mearelli1, Nicola Fiotti1, Nicola Altamura1, Irene Paoli1, Chiara Casarsa1, Maurizio Rusci2, Gianni Biolo1

1Unit of Clinica Medica Generale e Terapia Medica, Department of Medical Surgical and Health Sciences, University of Trieste, Italy; 2Laboratory Medicine Ospedale Sant’Antonio, San Daniele Del Friuli, Italy

Critical Care 2013, 17(Suppl 4):P17; doi:10.1186/cc12917

Background: More than 50% of all septic patients admitted to intensive care departments derive from intermediate care units (ICU). Biomarkers represent the most promising tool for early diagnosis of sepsis; but their accuracy in ICU has been largely disregarded [1]. Moreover, given the complexity of the septic pathophysiology, a panel of biomarkers could be more effective than a single one. For this reason we tested acute phase protein, cell surface, vasotonous related, coagulation system, and tissue hypoxia markers in early ruling in/out of sepsis in patients suffering from systemic inflammatory response syndrome (SIRS) [2-5].

Materials and methods: This prospective observational study included all SIRS [5] patients newly admitted to a medical ward from February to May 2012. Cases were diagnosed as sepsis or non-infective SIRS by clinical examination, cultures of the biological fluid, and imaging during a 7-day follow-up. Investigators were blinded to biomarker results. Survivors at 7 and 30 days were also assessed. Samples for procalcitonin (PCT), presepsin (sCD14-ST), pro-adrenomedullin (PRO-ADM), fibrin degradation products (FDP) and lactate were collected within 4 hours of admission. Their role in predicting diagnosis and survival, alone or in combination, have been investigated by receiver operating characteristic (ROC) curve, Youden index, relative risk and binary logistic regression.

Results: Among the 60 sepsis patients (microbiological and clinical sepsis), the most common sites of infection were the lung (67%), urinary tract (17%), abdomen (5%), and skin (8%). The sepsis group had significantly higher levels of PCT, sCD14-ST and FDP than the non-infective SIRS group. The area under the ROC was 0.80, 0.78, and 0.67 for FDP, PCT, and sCD14-ST respectively. Main results are reported in Table 1: the combination of FDP and PCT detected correctly 10 more cases, leaving misdiagnosed only nine out of 80 patients. ROC curves are reported in Figure 1. sCD14-ST (cutoff 1.317 ng/ml OR 12.2 (95% CI 2.6 to 65.5) P = 0.0002) and lactate (cutoff 20 mg/dl OR 11.9 (95% CI 2.23 to 62.5) P = 0.001) were comparable in predicting 7-day survival. Mortality at 30 days was significantly higher in patients with PRO-ADM level ≥4.09 nmol/l (OR 26 (95% CI 4.8 to 143) P = 0.000002). The Kaplan-Meier curves for PRO-ADM are reported in Figure 2.

Conclusions: In intermediate care setting patients, the combination of FDP and PCT could be useful for an early discrimination of sepsis from non-infective SIRS. PRO-ADM, sCD14-ST, and lactate should be considered as early indicators of more intensive ward care and precarious ICU admission.

Clinical manifestations, etiology and outcome of sepsis in pediatric patients admitted to the ICU

Tais C São Pedro1, André M Morcolli, Emilio CE Baracat

Department of Pediatrics, State University of Campinas, UNICAMP, Campinas, SP, Brazil

Critical Care 2013, 17(Suppl 4):P18; doi:10.1186/cc12918

Background: Sepsis still represents the leading cause of mortality among children and its etiology changes according to age, immune status and geographic location [1-4]. Prevention of this disease has key role in reducing morbidity and mortality and includes development and application of vaccines [5-7]. In 2010, pneumococcal and meningococcal C vaccines were introduced in the basic immunization schedule in Brazil. The application of these may already be influencing the etiologic profile of sepsis in childhood [7]. The evaluation of this profile, as well as the clinical manifestations and course of sepsis in the post vaccine, becomes essential for better clinical decision and effective therapeutic approach in hospitalized patients. The objective was to determine clinical manifestations, etiology and outcome of sepsis in patients admitted to a pediatric ICU.

Materials and methods: A retrospective cohort study, by collecting data from medical records of patients diagnosed with sepsis admitted to the pediatric ICU of Hospital Municipal Dr. Mario Gatti, Campinas, SP, from January 2011 to December 2012. The variables studied were: age, sex, vaccination schedule, etiologic agent identified in cultures and clinical outcome.

Results: Eighty-seven patients were included in the study (56 male, 31 female) with a mean hospital stay of 8.16 days, vasoactive drug use of 2.82 days and 5.33 days of mechanical ventilation. In total, 57/87 cultures were negative. Among the positive, the majority (21/30) was collected less than 48 hours after admission and the most frequent etiologies were: Gram-negative bacteria (10), Staphylococcus aureus (7) and Neisseria meningitidis (4). Two cultures were positive for Streptococcus pyogenes and only one for Streptococcus pneumoniae. Twenty-four (16.1%) patients died.

Mortality was higher in patients with incomplete immunization ($P = 0.047$). Among the cases with meningococcal etiology, 3/4 were not vaccinated.

**Conclusions:** The clinical group of patients diagnosed with sepsis showed short time of hospitalization, use of vasoactive drugs and mechanical ventilation. Mortality was high and higher in the group of patients with incomplete immunization. Among the causative agents, it was predominantly Gram-negative bacteria and *S. aureus*, no vaccine-preventable etiologies.

Introduction: The project ‘HUPE against sepsis’ seeks to emphasize the importance of early recognition of sepsis, in order to accelerate the implementation of measures associated with decreased mortality for severe sepsis. It is therefore important that the professionals involved in healthcare are attentive to quick detection of signs and symptoms associated with the condition. The objective was to identify the difficulties for the implementation of the protocol advocated by the Surviving Sepsis Campaign and adopted by the project ‘HUPE against sepsis’.

Materials and methods: The study was conducted in clinical medical and surgical wards, DIP, general duty, cardiac and ICUs of the Pedro Ernesto University Hospital (HUPE), totaling 11 inpatient units. In January 2013, a questionnaire was applied to doctors, nurses and nurse technicians, including effective, contractors and residents. This instrument contained closed questions, professional profile and was related to the topic in question.

Results: Fifty-one professionals participated in the study: 22 (43%) medical staff and 29 (57%) nurses. Of these, 12 were medical residents, and eight were nursing residents, all in the first year (approximately 78% of workers investigated). Most physicians (55%), 38% of nurses and 40% of nurses claimed to have greatest difficulty administering the first dose of antibiotics within up to 1 hour after the diagnosis. About 45% of doctors and 31% of nurses also reported difficulty in the distribution of materials to acquire the sepsis kit (which contains materials for deep venous puncture, invasive hemodynamic monitoring and collecting blood cultures). Physicians (41%) and nurses (40%) still reported as a problem going to the pharmacy to get the first dose of the antibiotic. Other limiting factors were also appointed: obtaining the vesical catheterization of delay (for hourly diuresis control); rapid identification of severe sepsis; printed data record of the protocol; samples of blood culture for aerobic; and peripheral venous access puncture.

Conclusion: The difficulties pointed out by the professionals investigated are common and include factors that prevent the correct and early implementation of the protocol, be they of institutional and/or professional responsibility. Seeking solutions to the problems raised allows a targeting of future actions to be developed, among them the constant updating and training of professionals involved in assistance for the patients investigated. This allows, also, the search for better institutional infrastructure appropriate to meeting the demands of the patient with severe sepsis.

Background: Neutrophils as a part of nonspecific immunity factors play a crucial role in antimicrobial resistance. Reactive oxygen species (ROS) are an important compound of the neutrophils' microbialidal action. Analysis of neutrophils' ROS production could provide valuable data on a phagocyte link of immunity [1]. A chemiluminescent (CL) assay being highly sensitive allows evaluating oxidative output of the cells in dynamics. Many studies on neutrophil CL in humans with different diseases have been published [2,3]. However, the results often vary between authors because of the lack of standardized method of CL analysis. So we have developed a methodology of neutrophils’ CL analysis according to the principles of evidence-based medicine.

Materials and methods: One hundred and twenty healthy donors and 17 ICU patients with second-third-degree burns participated in this study. We held an assay on the 1st, 8th and 15th day after injury and later; 37 observations in total. To dilute blood samples we used Hank balanced salt saline (HBSS) with glucose, pH 7.4. Luminol (Sigma-Aldrich) was dissolved in double-distilled water at 1 mM. N-formyl-methionyl-leucyl-phenylalanine (FMLP; Sigma-Aldrich) and 4-phorbol-12-myristate-13-acetate (PMA; Sigma-Aldrich) were diluted in dimethyl sulfoxide (MP Biomedicals, LLC) to make stock solutions that were dissolved in HBSS on the day of experiment. CL was evaluated by means of a chemiluminoimeter Lum-12 (Department of Biophysics, Moscow State University) [4].

Results: We substantiate an optimal experiment design in the context of obtaining the highest intensity of analytic signal and reproducible findings. Thus we have developed a method for evaluation of a neutrophil function, based on a step-by-step stimulation of the cells by PMA and FMLP. Using our approach, we investigated the distributions of CL characteristics for the population of 80 healthy donors. We obtained reproducible kinetic profiles with intensive flash and absent glow phase of emission in all of the samples. Profiles of ICU patients’ samples showed high intensity of both flash and glow phase of emission (Figure 1). Insufficient glow phase indicated subsequent development of severe septic complications.

Figure 1 (abstract P20) Kinetics of CL response in ICU patient and donor.
Conclusions: As a result we suggest a reliable and replicable method for the evaluation of a neutrophil function. Investigation of the glow phase of the emission is promising to forecast risks of septic complications; we constructed a range of values of adjusted CL glow amplitude at different neutrophil counts that indicates a low probability of SIRS and septic complications that could be useful for correction of intensive treatment tactics.

Acknowledgements: The author would like to express deepest appreciation to all those who provided the possibility to perform this research. The author wishes to thank Prof. YA Vladimirov and the team of Department of Biophysics at Moscow State University (Russia) and Dr MA Godkov for assistance and guidance with this study and for submitting of equipment and reagents. Also the author would like to thank Dr EN Kobzeva and Prof. Dr SV Smirnov for the opportunity to work with blood donors and ICU patients. Furthermore, the author would also like to acknowledge with much appreciation Dr VV Kulabukhov and the staff of the Department of Burn Resuscitation at Vishnevsky Institute of Surgery (Moscow, Russia) for their suggestions and encouragement.

Prediction of bacteremia in emergency department patients with suspected infection: an external validation of a clinical decision rule
Marie K Jessen1,2*, Julie Mackenhauer1, Anne Mette Sondrup Wulff Hvass2, Simon Skibsted1,2, Hans Kirkegaard1, Henrik C Schanheyder4, Nathan I Shapiro2
1Research Center for Emergency Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Research Department of Emergency Medicine, Aarhus University Hospital, Aarhus, Denmark; 3Department of Infectious Disease, Aarhus University Hospital, Aarhus, Denmark; 4Research Department of Emergency Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA

Background: Bacteremia is a common clinical condition with an incidence of approximately 140 to 160 per 100,000 person-years. Since sepsis is a time-critical diagnosis, identification of emergency department (ED) patients at risk of bacteremia is therefore a priority. The study objective was to validate a previously published clinical decision rule for predicting a positive blood culture in ED patients with suspected infection based on minor criteria, major criteria and a total score [1].

Materials and methods: This was a retrospective matched cohort study, set in a large urban academic tertiary ED at Aarhus University Hospital, Aarhus, Denmark with approximately 56,000 patient visits annually. Adult ED patients with blood cultures obtained from 1 January through 31 December 2011. ED patients with blood culture-confirmed bacteremia were matched 1:3 to patients with negative cultures. The outcome was true bacteremia. Features of the clinical history, co-morbid illnesses, physical observations and laboratory tests were used to evaluate the performance of the clinical decision rule including calculation of the total score (Table 1). We report operating characteristics and the summary statistic for the decision rule.

Results: Among 1,526 patients, 105 (6.9%) patients were classified with true bacteremia. The sensitivity of the prediction rule was 94% (95% confidence interval (CI) 88 to 98%) and specificity 48% (95% CI 42 to 53%). Positive and negative predictive values were 37% (95% CI 32 to 44%) and 96% (95% CI 92 to 99%), respectively. The area under the receiver-operating characteristics curve was 0.83 ± 0.02 standard error (Figure 1).

Conclusions: The clinical decision rule performed well in our ED setting and is likely to be a useful supplement to clinical judgment.

Figure 1 (abstract P24)
Logistic regression was performed to determine the independent mortality odds.

Results: Four thousand, nine hundred and fifty-two patients were enrolled at BIDMC and 483 patients at AUH. Overall mortality rates were 4% and 11% with mean ages of 58 ± 21 and 69 ± 16 years, respectively. The mortality rate increased with increasing number of organ dysfunctions: BIDMC: 0 organ dysfunctions, 0.6% mortality; 1 dysfunction, 3.3%; 2 dysfunctions, 7.8%; 3 dysfunctions, 15.9%; and ≥4 dysfunctions, 34.3%; and AUH: 2.2%, 6.7%, 17%, 41%, and 57% mortality (Figure 1). The number of organ dysfunctions remained an independent predictor after adjustment for age and Charlson Index (Table 1). The AUCs for the models were 0.82 and 0.87, respectively (Figure 2). The effect of specific types of organ dysfunction on mortality was largest for respiratory dysfunction (OR 3.57 (95% CI 2.5 to 5.1)) in the internal and for hematologic dysfunction (OR 33.57 (8.56 to 127.3)) in the external validation set (Table 2).

Conclusions: Using readily available criteria in the ED to assess the number of organ dysfunctions is a reliable tool in predicting in-hospital mortality in both validation sets and could assist in risk prognostication and aid with earlier, targeted therapy.

Lactate levels in emergency department patients across all causes of physiologic instability

Kimie Ødorf1,2*, Danielle Day1, Simon Skibsted1,2, Marie K Jessen1,2, Nicolaj Duus1,2, Nathan I Shapiro1, Daniel Henning1

1Research Center for Emergency Medicine, Aarhus University Hospital, Aarhus, Denmark; 2Research Department of Emergency Medicine, Beth Israel Deaconess Medical Center and Harvard Medical School, Boston, MA, USA

Background: Physiologic instability (PI) is a common, critical problem in the emergency department (ED) [1,2], and can have different underlying causes. The ability to determine the underlying cause of instability is paramount for early treatment and risk stratification [3]. Lactate has been shown to have prognostic value in some categories of unstable patients [4,5]. The objective of this study was to investigate how serum lactate concentrations differ across categories of PI and the association of lactate concentrations with clinical deterioration for each category.

Materials and methods: A prospective observational study of adult patients with PI at a university ED. PI was defined as lactate ≥4 mmol/L, or >5 minutes of heart rate (HR) ≥130, or respiratory rate (RR) ≥24, or shock index ≥1, or systolic blood pressure ≤90 mmHg. We excluded patients with no lactate measurements, isolated atrial tachycardia, seizure, intoxication, psychiatric agitation, or tachycardia due to pain. A physician retrospectively...
Figure 1 (abstract P25) Lactate levels across groups of physiological instability.

Figure 2 (abstract P25) Levels of lactate across groups of physiological instability stratified by deterioration. no/yes = deterioration present or not. (*) Significant differences between groups ($p < 0.05$).
categorized PI cause. Categories were defined as septic, cardiogenic, hemorrhagic, hypovolemic, or other. The primary outcome was deterioration, defined as acute renal failure (elevated creatinine to ≥2× baseline levels), intubation, vasopressors, or in-hospital mortality.

Results: We identified 1,156 patients with PI and excluded 324. Of the remaining, 304 did not have lactate measurements, leaving 528 for the analysis: 302 septic, 46 cardiogenic, 29 hemorrhagic, 57 hypovolemic, and 94 with another cause of instability. The differences in lactate levels between groups were not statistically significant (Figure 1). The lactate levels were statistically different between patients who deteriorated when compared with patients who did not deteriorate in the sepsis group (3.05 mmol/l vs. 1.91 mmol/l, \( P = 0.001 \)) and the other group (2.89 mmol/l vs. 1.94 mmol/l, \( P = 0.002 \)). No statistically significant differences were demonstrated for the cardiogenic, the hemorrhagic or the hypovolemic groups (Figure 2).

Conclusions: Lactate levels were not significantly different between the five groups with PI. However, in patients in the sepsis or other group, elevated lactate predicted deterioration. This was not demonstrated for the other causes of PI. This study suggests that in unstable patients lactate has the same likelihood of elevation between different causes of instability, but it may not have the same prognostic value for deterioration across underlying causes.

Background: Sepsis is the main cause of death in ICUs all over the world. Early detection of the pathogen is essential for appropriate antimicrobial treatment.

Materials and methods: To evaluate the reduction in time of antimicrobial adjustment therapy in patients with sepsis comparing a rapid molecular test (SeptiFast*) with conventional blood cultures, a randomized controlled clinical trial was conducted between October 2012 and May 2013 in a cardiology hospital. Adult patients staying more than 48 hours in hospital with clinical suspicion of sepsis were included in the study. Blood samples were collected for cultures (Bact/ALERT*) and SeptiFast* test immediately prior to initiation of antibiotic therapy. Patients were allocated into two groups. In the Intervention Group (GI), SeptiFast* results were communicated to the medical researcher and antimicrobials were adjusted. In the Control Group (GI), SeptiFast* results were not informed and therapy adjustment was based on the blood culture. Registered in Clinical trials.gov (NCT 01450538).

Results: Forty-six patients were included, 17 in GI and 29 in GII. Key data are shown in Table 1. GI therapy adjustment was done in 580 minutes compared with 3,007 minutes in GII (\( P = 0.004 \)).

Conclusions: The rapid molecular test (SeptiFast*) reduced the time for adjustment of antibiotic treatment in comparison with conventional blood cultures in critically ill sepsis patients.

Comparison between inflammatory biomarkers procalcitonin, IL-6 and C-reactive protein for infection diagnosis and fever evolution in neutropenic patients, submitted to hematopoietic stem cell transplantation
Karim Schmidt Rodrigues Massearo1, Rodrigo Macedo2, Maria Aparecida Shikanai-Yasuda1, Silvia Figueiredo Costa1
1Department of the School of Medicine of Universidade de São Paulo, Brazil; 2Fannem Ltd, Brazil, São Paulo, Brazil; 3Infectious and Parasitology Diseases, Department of the School of Medicine of Universidade de São Paulo, Brazil
Critical Care 2013, Volume 17 Suppl 4 http://ccforum.com/supplements/17/S4
Page 20 of 59

Background: Biomarkers were assessed during neutropenic fever in hematopoietic stem cell transplantation (HSCT). The objective was to assess serum values of C-reactive protein (CRP), procalcitonin (PCT) and IL-6 to identify infection in HSCT and risk factors for death.

Materials and methods: Prospective study with 296 patients submitted to autologous or allogeneic HSCT. PCT, CRP and IL-6 were assessed at the following moments: afibrile neutropenia, fever, 24 hours upon fever, 72 hours upon fever and long-lasting fever. Patients were classified into groups (I, afibrile; II, fever of unknown origin; and III, clinically or microbiologically proven fever). ROC curves, sensitivity, specificity, and multivariate analysis were used to evaluate factors associated with death.

Results: One hundred and ninety patients had fever. Mean and median levels of IL-6 at fever onset in group I with regard to group II (P = 0.013) presented significantly higher values. Levels of CRP in group I differed significantly from those found in group II (P < 0.05). Groups differed in levels of IL-6 and CRP at fever onset. Group II presented IL-6 and CRP concentrations significantly lower than group III. Cutoff values of PCT: fever onset, 24 hours upon fever, 72 hours of fever, and long-standing fever were: 0.32; 0.47; 0.46 and 0.35 μg/l. At fever onset, sensitivity was 52.3 and specificity 52.6 for infection diagnosis. Best cutoff values of CRP for fever onset, 24 hours upon fever, 72 hours upon fever and long-standing fever were: 79, 120, 108 and 72 mg/l. At fever onset, sensitivity was 55.4 and specificity was 55.1. Best cutoff values of IL-6 for fever onset, 24 hours upon fever, 72 hours upon fever and long-standing fever were: 34, 32, 16 and 9 pg/ml. At fever onset, sensitivity and specificity were: 59.8 and 59.7. In the autologous group, IL-6 presents significant values at initial moments. Independent risk factors identified in the multivariate analysis were: related donor, unrelated donor, Gram-negative infection, DHL ≥390 UI/l, urea ≥225 (mg/dl) and CRP ≥120 (mg/l).

Conclusions: IL-6 and CRP are associated with the early diagnosis of clinically or microbiologically confirmed infection in post-HSCT febrile neutropenia. The association of the three biomarkers did not present any advantage, nor did it improve diagnostic accuracy. IL-6 was the only biomarker significantly associated at an early stage with infection when assessed only in patients submitted to autologous HSCT. The independent variables associated with death were: allogeneic transplantation, Gram-negative infection, DHL ≥390 UI/l at fever onset and urea ≥225 mg/dl at fever onset and CRP ≥120 mg/l.

Severe pneumonia in critically ill cancer patients: clinical outcomes and a comparison between healthcare-associated pneumonia and community-acquired pneumonia
Liga SCF Robelito1, Luciano CP Azevedo1, Henrique Augusto de Souza2, Viviane Bogado Leite Torres1, Maria Ma Rosolem1, Jose Roberto Lapa e Silva1, Marcio Soares1,2,3,4,5, Jorge IF Salluh1
1Postgraduate Program of Internal Medicine, Universidade Federal do Rio de Janeiro, Brazil; 2Hospital Sirio-Libanés, São Paulo, Brazil; 3Hospital Barra Dor, Rio de Janeiro, Brazil; 4D’Or Institute for Research and Education, Rio de Janeiro, Brazil; 5Postgraduate Program, Instituto Nacional de Câncer, Rio de Janeiro, Brazil
Critical Care 2013, 17(Suppl 4):P28; doi:10.1186/cc12928

Background: Pneumonia is the most frequent source of infection in cancer patients and accounts for 50% of all cases of septic shock. Frequently cancer patients attend a hospital for several treatments and an event of pneumonia in this scenario is called healthcare-associated pneumonia (HCAP). The objective was to compare HCAP and CAP in cancer patients by current ATS CAP/HCAP definitions, comparing the population and morbidity risks of both groups.

Materials and methods: A prospective cohort study was performed from 2002 to 2011 at Instituto Nacional de Cancer and Hospital Sirio-Libanes, Brazil. Adult patients (>18 years) with a definite diagnosis of cancer and presenting with pneumonia (not acquired in the hospital setting) were evaluated at ICU admission. Demographic, clinical and laboratory data were collected during the first day of ICU including the CURB-65, the SAPS II, the SOFA score, comorbidities, Performance Status and cancer-related and treatment-related data.

Results: A total of 268 patients were admitted to the ICU with pneumonia and classified as CAP (n = 109/40.7%) and HCAP (n = 159/59.3%). There were 187 (69.8%) patients with solid tumors and 81 (30.2%) patients with hematological malignancies. One hundred and sixty-seven (63.9%) patients had septic shock at ICU admission. ICU and hospital mortality rates were 45.5% and 67.9%. When we compared CAP and HCAP populations, we observed similar characteristics and outcomes in both groups. As expected, higher severity of illness, organ failures, need for life-sustaining therapies and failure of NIV were associated with increased mortality. In a multivariate analysis, mechanical ventilation in the ICU (OR 2.52 (1.19 to 5.32)), dialysis in the ICU (OR 3.86 (1.23 to 12.10)) and higher severity of illness (SAPS2 per point OR 1.03 (1.01 to 1.05)) were associated with increased hospital mortality whereas successful noninvasive ventilation was associated with lower mortality (OR 0.32 (0.13 to 0.77)). The model showed good discrimination (AROC 0.832).

Conclusions: We believe that cancer patients are a distinct group of patients with pneumonia regardless of HCAP or CAP classification. They have specific characteristics and predictors of outcome, and treatment should be based on their clinical characteristics and local microbiologic profiles.

Sepsis-associated brain dysfunction in critically ill patients
Cristiane Damiani Tomasi1, Franciele Vuolo1, Larissa de Souza Constantino1, Dêbora Mozena Dall’Igna1, Eduardo Mazón1, Renato Maioleti1, João Quevedo1, Cristiane Ritter1, Antonio Texeira1, Felipe Dal-Pizzol1
1Laboratório de Fisiopatologia Experimental and Instituto Nacional de Ciência e Tecnologia Translacional em Medicina, Programa de Pós-Graduação em Ciências da Saúde, Unidade Acadêmica de Ciências da Saúde, Universidade do Extremo Sul Catarinense, 88806-000, Criciúma, SC, Brazil; 2Departamento de Bioquímica e Imunologia, Instituto de Ciências Biológicas da UFMG, Belo Horizonte, MG, Brazil

Background: Delirium is a common occurrence in critically ill patients and is associated with an increase in morbidity and mortality [1]. Some evidence suggests that septic patients with delirium may differ from a general critically ill population. In a subgroup analysis of the MENDS study, a benefit of dexmedetomidine sedation over lorazepam was only evident in septic patients [2]. The aim of our study was investigate the relationship between systemic inflammation and the development of delirium in septic and nonseptic critically ill patients.

Materials and methods: We performed a cohort study in a 20-bed mixed ICU that included consecutive patients admitted for more than 24 hours. Delirium was diagnosed using the Confusion Assessment Method for the Intensive Care Unit (CAM-ICU). Coma was defined as a Richmond Agitation Sedation Scale (RASS) score of -4 or -5. Blood samples were collected within 12 hours of enrollment for determination of TNFα, soluble TNF receptor (STNF-R1) and STNF-R2, IL-1β, IL-6, IL-10 and adiponectin.

Results: Seventy-eight patients were included in the study: 26 nonseptic/ nondelirium (control), 13 nonseptic/delirium (delirium), 21 septic/nondelirium (septic) and 18 septic/delirium (sepsis-associated delirium (SAD)). From all analyzed biomarkers only STNFR1, STNFR-2 and adiponectin were independently associated with delirium occurrence, but none of these biomarkers had a significant interaction with sepsis. In contrast, there was significantly interaction between sepsis and IL-1β suggesting that this cytokine is differentially modulated when comparing septic and nonseptic patients with delirium.
Conclusions: The association between IL-1β and delirium is different in septic versus nonseptic patients, suggesting that mechanisms which drive SAD may differ from that of nonseptic ICU delirium.

Clinical features and prognosis of patients co-infected with HIV and tuberculosis in the ICU
Ana Carla Peccei Carvalho Ribeiro da Silva, Rodrigo T Amâncio, Denise Medeiros, Emerson C Mesquita, André M. Japiassú, Fernando Bozza Instituto de Pesquisa Clinica Evandro Chagas, FIOCRUZ, Rio de Janeiro, Brazil Critical Care 2013, 17(Suppl 4):P30; doi:10.1186/cc12930

Background: Despite advances in treatment, tuberculosis (TB) remains a global health threat and is the leading co-infection among Brazilian HIV-infected patients [1-4]. Mortality of TB in the presence of sepsis and shock septic can be as high as 67%, with respiratory failure being the leading cause of ICU admission [2,3,5]. Clinical factors that enhance mortality among HIV-TB patients are yet to be explored.

Materials and methods: We retrospectively accessed data of HIV/AIDS critically ill patients from January 2007 until May 2012, at a referral infectious diseases hospital. All patients admitted to the ICU with laboratory-confirmed TB were included in the analysis. Demographic and clinical data were categorized for survivors and nonsurvivors and the results were displayed as frequency (%), median values and interquartile range.

Results: Fifty patients were included. Hospital mortality was 48%. Age was 31.5 years (26.5 to 42.75) in the survivors group versus 33.5 years (30 to 45.25) in nonsurvivors (P = 0.25), and the SAPS II score was 44.5 (37.25 to 55.75) versus 47.25 (38.75 to 54.25) (P = 0.58). The most common TB presentation was disseminated disease (56%) followed by pulmonary (44%), with no difference according to survival. The delta of days between ICU admission and beginning of TB treatment was not different between groups. Rifampicin (94%), pyrazinamide (94%), isoniazide (92%) and ethambutol (76%) were administered in the majority of patients, while fluoroquinolones and aminoglycosides were administered in 64% and 54% respectively. Nonsurvivors presented with more elapsed time since HIV diagnosis (1 (1 to 7) vs. 26 (5 to 72), P = 0.10) lower nadir CD4 cell count (72.5 (27.5 to 133.5) vs. 24 (14.5 to 63), P = 0.03); and HAART initiated within 30 days after admission (62% vs. 29%, P = 0.03, odds ratio 3.9 (95% CI 1.2 to 12.7)). The main reason for ICU admission was respiratory failure (70%). Nonsurvivors needed mechanical ventilation (88% vs. 48%, P = 0.006) and vasopressors (71% vs. 41%, P = 0.05) more frequently. Neurological dysfunction was more common in nonsurvivors (79% vs. 41%, P = 0.01, odds ratio 5.2 (95% CI 1.5 to 18.2)). After multivariate analysis, neurological dysfunction was associated with higher mortality, while HAART in the first 30 days of hospitalization was a protective associated factor.

Conclusions: The disseminated form was the most common presentation of TB in HIV/AIDS critically ill patients. Nonsurvivors were more prone to multiple organ dysfunction syndrome, with neurological dysfunction associated with hospital mortality. The administration of HAART within 30 days of hospitalization was associated with survival.

Background: Sepsis is a complex and multifactorial syndrome, whose incidence, morbidity and mortality have been increasing worldwide. The knowledge of clinical, epidemiological and hemodynamic parameters responsible for its evolution, diagnosis and treatment are still the subject of many studies. Therefore, this study aims to evaluate clinical, laboratory and hemodynamic parameters of morbidity and mortality in patients with severe sepsis and septic shock.

Materials and methods: As the diagnostic criteria of the systemic inflammatory response syndrome (SIRS) are very sensitive and very little specific, we selected patients with severe sepsis and septic shock in the first 24 hours of ICU admission, 18 years old or more, with two general and one or more inflammatory criteria of SIRS (ACCP/SCCM/2003). Patients with pathologies that could confound clinical and laboratory evaluations and advanced comorbidities or on immunosuppressive drug therapy were excluded. The ICU had 35 beds, five of them are reanimation beds located in Table 1(abstract P31) Demographic and clinical characteristics observed in patients with severe sepsis and septic shock

Multivariate analysis of variables associated with mortality observed in patients with severe sepsis and septic shock in the ICU/HRTN between April 2011 and October 2012 (n = 72). CI, confidence interval; HR, hazard ratio; MAP, mean arterial pressure.

the emergency room (ER). The same intensivist team assists all patients in the ER and during ICU permanence. The principal investigator did not perform any orientation or intervention in the treatment of selected patients. Clinical (age, sex, infection focus, fluid balance, hemodialysis, use of corticosteroids, antibiotic therapy, APACHE II, SOFA), laboratory (blood cell counting, lactate, creatinine, bilirubin, glucose, cortisol, NT-proBNP, C-reactive protein (CRP), procalcitonin (PCT), Troponin I), hemodynamic (blood pressure, heart rate, left ventricular systolic function (echocardiography)) and respiratory parameters (respiratory rate, PaO2/FiO2), PEEP and peak inspiratory pressure (PPIP) were analyzed from ICU admission until discharge or death. Echocardiography was performed at 48 hours and on the 10th day after ICU admission.

Results: Seventy-two patients (64% male), mean age 52 ± 19 years, were consecutively included, 21% (15/72) with severe sepsis and 79% (57/72) with septic shock. Mortality was 18% (13/72), of these 21% (3/13) for severe sepsis and 79% (10/13) for septic shock. Median APACHE II score was 28 (16 to 37) and SOFA score 6 (5 to 10) (Table 1). There was positive correlation between mortality with: male gender, APACHE II, SOFA, positive 24-hour fluid balance, hemodialysis indication, corticosteroid use, leukopenia, lactate, NT-proBNP and PCT levels (Table 2). From univariate analysis, practically the same significant association with mortality was observed (Table 3). In addition, the final multivariate Cox model showed
that male gender, hypotension (first 24 hours), leukopenia and positive fluid balance (first 24 hours) had an impact on mortality (Table 4). Glycemic control and early antibiotic use were not relevant.

**Conclusions:** Precocious treatment, judicious fluid management and individualized care showed benefit in the treatment of patients with severe sepsis, septic shock.

**P32**

Risk factor for mortality associated with carbapenem-resistant Enterobacteriaceae infections

Cláudia MDM Camilo1, Cintia MC Giron1, Marcos T Tanita1, Jamile Vale1, Larissa Oliveira2, Ana P Marchi2, Silvia F Costa2

1Universidade Estadual de Londrina, PR, Brazil; 2Universidade de São Paulo, SP, Brazil

Critical Care 2013, 17(Suppl 4):P32; doi:10.1186/cc12932

**Background:** Antimicrobial resistance has emerged and increased in the last 25 years, complicating the treatment of nosocomial infections, especially for extended-spectrum beta-lactamase Enterobacteriaceae (ESBL). Furthermore, disseminated use of invasive procedures, particularly in ICU patients favors the emergence of multiresistant pathogens. More recently, Enterobacteriaceae has developed a new mechanism of antimicrobial resistance and became resistant to carbapenems. Among Enterobacteriaceae resistant to carbapenem, Klebsiella pneumoniae is the most common. These pathogens manifest resistance to most of antimicrobials tested and are associated with high mortality rates. The aim of this study is to describe epidemiologic data about nosocomial infections due to carbapenem-resistant Enterobacteriaceae and identify risk factors for death.

**Materials and methods:** Longitudinal study evaluating patients with infections caused by carbapenem-resistant Enterobacteriaceae, isolated from blood, urine, tracheal secretions, skin and soft tissues, treated accordingly to the Brazilian Society of Infectious Diseases guidelines, from March 2011 to December 2012. Acute Physiology and Chronic Health Evaluation (APACHE II) was calculated to evaluate severity of disease and Sequential Organ Dysfunction Assessment (SOFA) to measure organ dysfunction. Comorbidities were classified according to Charlson comorbidities index list. Patients were followed until hospital discharge.

**Results:** During the study period, 174 nosocomial infections caused by carbapenem-resistant Enterobacteriaceae were identified in 148 patients. All infections were microbiologically documented and 136 (78.2%) occurred in patients who were admitted to the ICU. Sepsis (17.8%), polytrauma (14.4%), cardiovascular disease (13.8%) and respiratory disease (11.5%) were the most common diagnosis. Most of the patients (78%) had one or more comorbidities according to Charlson criteria, and 57/148 (43.2%) patients had three or more comorbidities. Median APACHE II was 20.7 (7 to 38) and median SOFA at ICU admission was 7 (0 to 14). Median length of hospital stay was 43 (6 to 230) days. K. pneumoniae was the most common enterobacteria (86.8%), followed by Enterobacter spp. (8%). The mechanism of resistance was identified as Klebsiella pneumoniae carbapenemase (KPC) present in 77.2% of K. pneumoniae infections. Shock was present in 81/148 (46.6%) patients and dialysis was used in 62/148 (35.6%). Hospital mortality was 62.6% and associated mortality was 33.3%. Multivariate analysis identified dialysis and pneumonia as independent risk factors for death.

**Conclusions:** Many patients infected with carbapenem-resistant Enterobacteriaceae were identified, and most of them were caused by carbapenemase producing bacteria. These infections were associated with high mortality rate. Shock, dialysis, pneumonia, SOFA discharged >6 and APACHE >20 were identified as independent risk factors for mortality.

Rapid response team: the early identification of septic patients

Andreia Pardini*, Michele Jaures, Sandra Christina Pereira Lima Shiramizo Hospital Israelita Albert Einstein, São Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P33; doi:10.1186/cc12933

**Background:** Rapid response teams (RRTs) represent an intuitively simple concept: when a patient demonstrates signs of imminent clinical deterioration, a team of providers is summoned to the bedside to immediately assess and treat the patient with the goal of preventing ICU transfer, cardiac arrest, or death [1]. Patients whose condition deteriorates acutely while hospitalized often exhibit warning signs (such as abnormal vital signs) in the hours before experiencing adverse clinical outcomes. Sepsis is an illness in which the body has a severe response to bacteria or other germs. This response may be called systemic inflammatory response syndrome (SIRS) [2]. The criteria for calling the RRT are the same as/similar to symptoms of sepsis. We aimed to describe the various criteria for calling the RRT for patients who developed sepsis, initial treatment before transfer to the ICU or step-down unit and outcomes.

**Materials and methods:** This retrospective study was conducted in 2012 in the ICU of Hospital Israelita Albert Einstein, a general, private tertiary hospital. During the study period, the hospital had 614 beds, 6.7% (41/614) of which were in the ICU and 13.5% (83/614) were the step-down unit. We included patients 18 years of age or older diagnosed with severe sepsis and septic shock treated by the RRT and transferred to the ICU or step-down unit for study retrospectively. We excluded patients who had contraindications to cardiac resuscitation. Severe sepsis and septic shock were defined according to the American College of Chest Physicians/Society of Critical Care Medicine Consensus Conference definitions [3]. Data regarding age, gender, Simplified Acute Physiology Score II (SAPS II) [4], presence of the following comorbidities, criteria for calling the RRT, initial treatment for sepsis, length of ICU and total stay, and patient outcome were recorded.

**Results:** Sixty-five of 41 (63.1%) were males, 23 (35.4%) were transferred to the step-down unit and 42 (64.6%) were transferred to ICU. Their age was 64.7 ± 17.8 years. SAPS II score was 57.8 ± 12.8, length of stay was median 26 days, ICU stay was median 3 days. The treatment of sepsis

Data presented as n (%), mean (± SD) or median (IQR).
was also initiated in the ward. The serum lactate + measured blood culture was 40 (63.5%) and fluid administration was 41 (64.1%) (Table 1). Pressing the RRT was in 43 (66.2%) cases by the staff member with significant concern about the patient’s condition, 27 (41.5%) cases by changes in systolic blood pressure, and 23 (35.4%) cases due to change in oxygen saturation (Table 2).

Conclusions: The criteria for calling the RRT can support the prompt identification of patients who have sepsis and prevent disease progression. Furthermore, the treatment may also be performed in the ward and may result in a reduction in mortality.

P34 Knowledge of the nurse in advanced life support and the impact of continuing education in cardiopulmonary arrest in the ICU
Daniella Fernandes Mendonça1, Denise de Fátima Gomes Machado2, Renata Cristina Barbosa Silva2, Camila Medeiros Cruvinel Cunha3, Daniella Fernandes Mendonça1*, Denise de Fátima Gomes Machado2, Renata Cristina Barbosa Silva2, Camila Medeiros Cruvinel Cunha3

Background: Knowledge of the nurse in advanced life support and the impact of continuing education in cardiopulmonary arrest in the ICU. Faced with the complications of cardiopulmonary arrest (CPA) in the ICU it is important for nurses to be prepared for emergency actions, mastering the techniques of care and well-trained staff. The objective was to identify and describe the knowledge of the nurse in advanced life support (ALS) and the impact of continuing education on CPR in ICU.

Results: Twenty-six publications found and gave rise to two categories. First, the identification of clinical signs and CPR maneuver by the nursing staff and the nurse in the PCR are essential for successful resuscitation; the authors agree that the service systematized-based SAPV protocol is essential for there to be success in CPR. Recognition theoretical and practical skills of the staff are among the most important determinants of the success rates of RC [1]. Thus, it is necessary that health professionals, especially nursing staff, be aware of the clinical signs of PCR. Furthermore, the residence time of the professional nursing staff in the ICU causes them to gain more experience, making it easier to identify clinical signs and cardiac rhythms [2,3]. Second, the impact of continuing education on quality of nursing care in a PCR: the proper training of the nursing staff, especially those that operate in the ICU, is vital for emergency treatment PCR. Identifying the theoretical and practical knowledge of staff about the PCR and CPR is an important prerequisite for planning a training service [2]. The nurse as team leader and organizer of the ICU is the right professional to establish measures to be taken at the time of the PCR. The nurse has a responsibility to properly distribute the measures to be implemented at the time of service of the PCR, identifying it early and minimizing damage [4].

Conclusion: Continuing education has significant impact in improving the level of knowledge of nursing professionals, leading to survival of patients in a hospitalized ICU, as it ensures the identification of the signs and symptoms of CRP in patients in the ICU.

P35 Prevalence of vitamin D deficiency among children with sepsis, its association with sepsis severity and its outcome in a pediatric ICU
Ponnarneni Satheesh1, Savita Verma, Sunit Singh, Arun Bansal
Department of Paediatrics, Post-Graduate Institute of Medical Education & Research (PGIMER), Chandigarh, India

Background: Increased prevalence of vitamin D deficiency (VDD) in sepsis and its association with sepsis severity has been documented in adults [1-3]. However, data on the pediatric population are scarce. This study aims at assessing the prevalence of VDD (25-hydroxyvitamin D (25(OH)D) level <20 ng/ml) among children with sepsis in developing nations and its implication on sepsis severity.

Materials and methods: A prospective observational study conducted between January and December 2012. During the study period all consecutive PICU admissions between the ages of 1 and 12 years were screened for sepsis at the time of admission to the ICU. Out of 613 PICU admissions, 124 patients satisfying the criteria for sepsis [4] were randomly enrolled and followed up throughout the hospital stay. Patients with an immunsuppressed state or receipt of vitamin D within the 3 months prior to hospital admission were excluded. A control group comprising of 40 healthy children was also included for comparison with the general population. The serum 25(OH)D level was measured in all patients with sepsis within 24 hours of admission to the PICU. Severity of sepsis was assessed using the Pediatric Risk of Mortality III (PRISM III) score and the daily Sequential Organ Function Assessment (SOFA) score.

Results: Patients with sepsis had low 25(OH)D levels compared with healthy controls (P = 0.04). Median 25(OH)D level among patients was 19.7 ng/ml (interquartile range [IQR]: 12.5, 31.2) and median 25(OH)D level among controls was 30.4 ng/ml (IQR: 22.1, 38). Prevalence of VDD was high among patients 51% (95% confidence interval (CI), 42 to 59) compared with the VDD of 17% (95% CI, 8 to 32) in healthy controls (P < 0.001) (Table 1). No significant correlation was found between vitamin D level and PRISM III score or daily SOFA score. Out of 19 deaths, 17 (90%) deaths occurred in patients with vitamin D deficiency and insufficiency (odds ratio 3.09, 95% CI: 0.6 to 20.7). However, the difference in mortality was not statistically significant (P = 0.58). Factors such as septic shock, multiorgan
dysfunction syndrome (MODS), duration of mechanical ventilation, blood
culture positivity, hypocalcemia and length of PICU stay were not modified
by the presence of VDD (Table 2).

Conclusions: We found a high prevalence of VDD among children with
sepsis when compared with healthy children but VDD was not associated
with the severity of sepsis or its outcome.

Acknowledgements: This study was carried out as a MD thesis, with
support from the institute (PGIMER, Chandigarh, India)

Background: Renal transplantation is the treatment of choice for end-
stage renal disease as it is cost-effective, and improves survival and quality
of life as compared with maintenance dialysis [1,2]. However, the need for
immunosuppression increases the hazard of septic complications [3]. Sepsis
is one of the leading causes of death among renal transplant recipients and
little is known about its characteristics in this population [4,5]. The aim
of this study was to evaluate the factors associated with mortality in renal
transplant patients admitted to the ICU with severe sepsis and septic
shock.

Materials and methods: We conducted a single-institution retrospective
observational cohort study in consecutive renal transplant patients admitted
to the ICU with severe sepsis or septic shock in a public high-volume kidney
transplant center from 1 June 2010 and 31 December 2011. We registered
demographic data, transplant characteristics and sepsis management to
identify predictive factors of ICU, hospital and 1-year mortality.

Results: A total of 190 patients were enrolled. The mean age was 51 ±
13 years, 115 (60.5%) were male, 122 (64.2%) were deceased donors,
median APACHE was 20 (16 to 23) and median admission SOFA was 5 (4 to
8). The most common source of infection was respiratory (59.5%) followed
by urinary tract (16.8%). Tachypnea, tachycardia, fever, hypothermia,
leukocytosis and leukopenia were present in 74.7%, 67.9%, 24.2%, 6.3%,
26.3% and 16.3% of the patients. The most prevalent dysfunction was
respiratory (68.4%) followed by cardiovascular (41.1%) and renal (40.5%).
The median time between transplantation and the septic event was 2.1 (0.6
to 7.8) years. The duration of organ dysfunction before the diagnosis of sepsis
was 2.5 (1.1 to 5.2) hours. The median length of ICU and hospital stay was
6 (3 to 13) and 20 (12 to 35) days, respectively. Hospital and 1-year
mortalities were 38.4% and 42.6%, respectively. In the multivariate analysis,
male gender, the variation in the SOFA score after the first 24 hours, the
need for mechanical ventilation, the presence of hematologic dysfunction,
being admitted from the wards and AKI stage 3 were predictors of hospital
mortality.

Conclusions: In the present study, independent factors associated with
mortality were related to features of sepsis severity and not to factors
associated with transplantation. Another interesting finding was the low
frequency of signs of systemic inflammatory response.

**Stratifying septic patients using lactate: severe sepsis and cryptic, vasoplegic and dysoxic shock profile**

Otavio T Ranzani1-4, Mariana B Monteiro1, Elaine M Ferreira1, Fernando Leibel1, Sergio Ricardo Santos1, Flavia R Machado2,3, Danilo T Noritomi1

1Hospital Paulistano, São Paulo, Brazil; 2Disciplina de Emergências Clínicas, Hospital das Clínicas, Universidade de São Paulo, Brazil; 3Latin America Sepsis Institute, São Paulo, Brazil; 4Disciplina de Anestesiologia, Escola Paulista de Medicina, Universidade Federal de São Paulo, Brazil

**Critical Care** 2013, 17(Suppl 4):P37; doi:10.1186/cc12937

**Background:** The current consensus definition of severe sepsis and septic shock includes a heterogeneous profile of patients under the same definition. Although the prognostic value of hyperlactatemia in sepsis is well established, hyperlactatemia can be found both in severe sepsis and septic shock patients. We sought to compare features and outcomes of septic patients stratified by two factors: the presence of hyperlactemia and persistent hypotension.

**Materials and methods:** This was a secondary analysis of a multicenter observational study from 10 private hospitals in Brazil (Rede Amil-SP) aiming to evaluate the impact of a multifaceted program to implement the Surviving Sepsis Campaign bundles. We retrieved 1,948 septic patients with an initial lactate level collected within the first 6 hours of diagnosis. Based on previous literature, we stratified them into four groups according to the presence of hypoperfusion (lactate >4 mmol/l) and/or persistent hypotension despite adequate fluids: 1. severe sepsis (without both criteria); 2. cryptic shock (hypoperfusion without persistent hypotension) [1]; 3. vasoplegic shock (persistent hypotension without hypoperfusion); and 4. dysoxic shock (with both criteria) [2].

**Results:** Severe sepsis was found in 1,018 (52%), cryptic shock in 549 (28%) and dysoxic shock in 219 (12%) patients. Mean age was 60 years, 47% were male and the majority was presented similar SOFA score to patients in the cryptic shock group (P = 0.20). Over 28-day crude survival was different between groups (P < 0.001), being higher for the severe sepsis group (69%, P < 0.001 vs. other), similar between cryptic and vasoplegic shock (53%, P = 0.39) and lower for dysoxic shock (38%, P < 0.001 vs. other). In an adjusted analysis considering age, APACHE II and SOFA scores (P < 0.001 for both), dysoxic shock being the most severe group. In post-hoc analysis, patients in the severe sepsis group presented similar SOFA score to patients in the cryptic shock group (P = 0.20).

**Conclusions:** Current definitions for severe sepsis and septic shock include four different phenotypes, which should be considered for epidemiology purposes, customizing treatment goals and inclusion criteria for future studies. Although previous studies showed similar outcomes between cryptic shock and overt septic shock (vasoplegic and dysoxic profile), we demonstrated that cryptic shock is similar only to vasoplegic shock.

**Antithrombin III concentrate may contribute to sepsis in nonovert disseminated intravascular coagulation**

Noriko Saito1, Mari Yokota, Ahmin Kim, Tomoyuki Harada, Munekazu Takeda, Mizuho Namiki, Arino Yaguchi

Department of Critical Care and Emergency Medicine, Tokyo Women’s Medical University, Tokyo, Japan

**Critical Care** 2013, 17(Suppl 4):P38; doi:10.1186/cc12938

**Background:** Antithrombin III (AT III) has been known to contribute to anti-inflammatory response as well as its anticoagulation. Our previous study showed AT III deficiency happened in the early stage of sepsis with no relation to disseminated intravascular coagulation (DIC) status. Whether AT III concentrate is a beneficial therapy or not for septic patients is still a controversial issue. Our hypothesis is that AT III concentrate may have efficacy as an anti-inflammatory for sepsis.

**Materials and methods:** From January 2009 to June 2013, adult septic patients with nonovert DIC whom were given AT III concentrate in our medicosurgical ICU were included in this study. DIC scoring was used with the definition of the International Society on Thrombosis and Hemostasis (ISTH). AT III concentrate was administered 30 to 60 U/kg intravenously every 24 hours for 3 days in the patients. Between before and after the AT III concentrate therapy, WBC (1/mm3), CRP (mg/dl), platelet (×109/μl), PT (seconds), fibrinogen (mg/dl), FDP (μg/ml), SOFA score and DIC score by ISTH were compared. Values are expressed as mean ± SD. Data were analyzed with Wilcoxon signed-rank test. P < 0.05 was considered significant.

**Results:** There were 157 patients (100 men, 57 women; age range 19 to 96 years [mean 70.0 ± 16.0]), and the 28-day mortality rate was 25.5% and APACHE II score was 17.2 ± 8.3. WBC, CRP, PT, and SOFA score were significantly improved after AT III concentrate therapy (13.411 ± 8.794 vs. 11.798 ± 6.562, P = 0.0007, 17.1 ± 11.5 vs. 13.9 ± 7.0, P = 0.0001, 16.3 ± 10.9 vs. 15.2 ± 5.3, P = 0.002, and 8.6 ± 3.6 vs. 7.7 ± 4.5, P = 0.005, respectively), although platelet was significantly decreased (15.8 ± 11.3 vs. 13.7 ± 11.3, P < 0.0001). There were no significant differences in fibrinogen, FDP and DIC score (464.7 ± 235 vs. 437.6 ± 185.4, P = 0.10, 25.1 ± 36.9 vs. 25.6 ± 36.2, P = 0.85, 2.0 ± 1.5 versus 2.3 ± 1.7, P = 0.06, respectively). One week after the therapy, SOFA score was significantly improved, while the DIC score did not change compared with before the therapy (6.1 ± 4.7, P < 0.0001 and 2.3 ± 1.7, P = 0.98).

**Conclusions:** In the patients with septic nonovert DIC, WBC, CRP and SOFA score were immediately improved after the AT III concentrate therapy, while fibrinogen, FDP and DIC score did not change. AT III concentrate may also contribute to anti-inflammatory without DIC status.

**P39**

**Intravenous immunoglobulin therapy could have efficacy in severe sepsis**

Ahmin Kim1, Mari Yokota, Noriko Saito, Munekazu Takeda, Tomoyuki Harada, Mizuho Namiki, Arino Yaguchi

Department of Critical Care and Emergency Medicine, Tokyo Women’s Medical University, Tokyo, Japan

**Critical Care** 2013, 17(Suppl 4):P39; doi:10.1186/cc12939

**Background:** Intravenous immunoglobulin (IVIG) administration has been approved to use for severe sepsis with antibiotics by the Ministry of Health, Labour and Welfare since 1980 in Japan. IVIGs are commonly used for severe sepsis and septic shock in Japan, while the international guidelines for management of severe sepsis and septic shock in 2012 suggest not using IVIG in adult patients. Our hypothesis is that IVIG administration has an efficacy for severe sepsis and septic shock.

**Materials and methods:** This retrospective observational study included all adult patients in our ICU who were administered IVIG for severe sepsis and septic shock from January 2011 to June 2013. IVIG was used at 5,000 mg/day every 24 hours for 3 days. We compared body temperature (°C), WBC (1/mm3), CRP (mg/dl), procalcitonin (ng/ml) and serum immunoglobulin G (lgG) (mg/dl; normal =870) before and after IVIG treatment. Values are expressed as the median. The Wilcoxon signed-rank test was used for the statistical analysis. P < 0.05 was considered significant.
Results: One hundred and fifty-one patients (85 men, 66 women; age range 23 to 96 (median 67.8)) were included in this study. The 28-day mortality after IVIG treatment was 13.9%. The SOFA score before IVIG treatment was 5.0. Values of WBC, CRP and procalcitonin were significantly decreased after IVIG treatment (10,905 vs. 9,805, P = 0.0001, 12.3 vs. 7.7, P = 0.0001, 2.4 vs. 1.7, P = 0.0003, respectively). Body temperature did not significantly change (37.4 vs. 37.2, P = 0.07). Serum IgG was significantly increased after the treatment (1,046 vs. 1,563, P = 0.003).

Conclusions: The present study has some limitations because of being a retrospective observational study. However, the mortality was quite low in the group of patients included in this study. Moreover, after IVIG treatment values of WBC, CRP and procalcitonin were improved. The median value of serum IgG before treatment was within the normal range, but after treatment was also significantly improved. There is a possibility that severe septic patients require additional IgG regardless of its normal concentrations in their blood.

**Usefulness of broad-range PCR in the etiologic diagnosis of sepsis**

Aline Gozzi*, Romulo R Lobo, José Maurício SC Mota, Antonio Pazin Filho, Bernardo A. Theil, Marcos C Borges

Department of Internal Medicine, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, SP, Brazil

Critical Care 2013, 17(Suppl 4):P42; doi:10.1186/cc12942

**Background:** Sepsis is responsible for a high rate of hospitalization and mortality. Traditional methods for bacterial isolation and identification, such as blood culture, have limitations in sensitivity and specificity and their results usually are not available before 48 to 72 hours. The PCR allows a rapid diagnosis of infectious agents. Broad-range PCR allows an earlier and more sensitive bacterial identification in just one reaction, even after the initiation of antibiotics. Therefore, this study evaluates the use of broad-range PCR in the etiologic diagnosis of septic patients, and compares it with traditional methods of culture.

**Materials and methods:** Thirty-five patients with sepsis, admitted to the Emergency Unit of Clinical Hospital of Ribeirão Preto Medical School, were included in the study. Clinical, laboratory, and culture data were collected at hospital admission. On the first day of admission, DNA extraction was performed from blood plasma and buffy-coat samples from all patients. Broad-range 16S rDNA PCR was then performed using two different pairs of primers (Bak11W/Bak2 and Taf/Tar).

**Results:** Eighteen (51%) patients were female; mean age was 58 ± 18 years; 15 (43%) had severe sepsis and 20 (57%) septic shock, and mortality was 54%. Mean C-reactive protein (CRP) was 14.39 ± 9.52 and 28 (80%) patients have levels of CRP greater than 5.0 ng/l. The primary site of infection was detected in all patients, 20 (57%) patients had respiratory tract infection, nine (26%) urgenetic tract infection, three (8.5%) cutaneous infection, and three (8.5%) other sites. Blood culture was positive in 14 (40%) samples. Broad-range PCR was positive in 19 (51%) samples. Only 10 (29%) samples were positive for both techniques. In 11 (31%) patients, neither blood culture nor PCR were positive.

**Conclusions:** Broad-range PCR was effective for diagnosis of bacterial infection in septic patients, and could be an option to be used in patients with severe sepsis and septic shock. Moreover, it is faster than blood culture and can detect bacteria even after the initiation of intravenous antibiotics. The combination of both techniques could increase the likelihood of etiologic diagnostic in septic patients.

**Clinical features and prognosis of patients co-infected with HIV and tuberculosis in the ICU**

Ana Carla Pecego*, Camila Ribeiro da Silva, Rodrigo T Arnâncio, Denise M Medeiros, Emerson C Mesquita, André M Japiassú, Fernando A Roza

Instituto de Pesquisa Clínica Evandro Chagas, Fundação Oswaldo Cruz, RJ, Brazil

Critical Care 2013, 17(Suppl 4):P43; doi:10.1186/cc12943

**Background:** Despite the advances in treatment, tuberculosis (TB) remains a global health threat and is the leading co-infection among Brazilian HIV-infected patients. Mortality of TB in the presence of sepsis and shock septic is still high, with respiratory failure being the leading cause of ICU admission. Clinical factors enhancing mortality among HIV-TB patients are yet to be explored.

**Materials and methods:** We retrospectively accessed data of HIV/AIDS critically ill patients from January 2007 until May 2012, at a referral infectious diseases hospital. All patients admitted to the ICU with laboratory-confirmed tuberculosis were included in the analysis. Demographic and clinical data were categorized for survivors and nonsurvivors and the results were displayed as frequency (%), median values and interquartile range.

**Results:** Fifty patients were included. Hospital mortality was 48%. Age was 31.5 years (26.5 to 43) in the survivors group versus 33.5 years (30 to 45) in nonsurvivors (P = 0.25), and SAPS II score was 44.5 (37 to 56) versus 47 (39 to 54) (P = 0.38). The most common TB presentation was disseminated disease (56%) followed by pulmonary (44%), with no difference according to survivorship. The interval of days between ICU admission and TB treatment was not different between groups. Rifampicin (94%), pyrazinamide (94%), isoniazide (92%) and ethambutol (76%) were administered in the majority of patients, while fluoroquinolones and aminoglycosides were administered in 64% and 54% respectively. Nonsurvivors presented with more elapsed time since HIV diagnosis (1 (1 to 7) vs. 26 (5 to 72), P = 0.10); lower nadir CD4 cell count (72.5 (27.5 to 133.5) vs. 24 (14.5 to 63), P = 0.05); and HAART initiated within 30 days after admission (62% vs. 29%, P = 0.03; odds ratio 3.9 (95% CI 1.2 to 12.7)). The main reason for ICU admission was respiratory failure (70%). Nonsurvivors needed mechanical ventilation (88% vs. 48%, P < 0.01) and vasopressors (71% vs. 41%, P = 0.05) more frequently. Neurological dysfunction was more common in nonsurvivors (79% vs. 41%, P = 0.01, odds ratio 5.2 (95% CI 1.5 to 18.2)). After multivariate analysis, neurological dysfunction was associated with hospital mortality, while HAART in the first 30 days of hospitalization was a protective associated factor.

**Conclusions:** Disseminated TB was the most common presentation in HIV/AIDS critically ill patients. Nonsurvivors were more prone to multiple organ dysfunction syndrome, and neurological dysfunction was associated with hospital mortality. The administration of HAART within 30 days of hospitalization was associated with survival.

**P44**

**Sepsis care protocol: initial evaluation at a university hospital in southern Brazil**

Fabiano Ramos*, Manilane P Silva, Paola H Alves, Michèle S Borges, Miriane MS Moretti, Georgia L Silva, Letícia G Lobo, Silvia PT Soares Hospital São Lucas, Pontifícia Universidade Católica Rio Grande do Sul, Porto Alegre, Brazil

Critical Care 2013, 17(Suppl 4):P44; doi:10.1186/cc12944

**Background:** Sepsis is a systemic inflammation caused by severe infection. It is a life-threatening condition, progresses rapidly, and affects multiple system functions. An evidence-based medical sepsis bundles model has been used for sepsis care in clinical practice. All patients who have at least two signs or symptoms of systemic inflammatory response syndrome (SIRS) secondary to an infectious process are considered septic. Sepsis is the leading cause of death in ICUs and a major cause of late hospital mortality rate, exceeding the acute coronary syndromes and neoplasms. Mortality in Brazil reaches 60%, while the world average is around 30%, overcoming countries such as India and Argentina. The early recognition and treatment of these patients are key to reducing mortality. The aim of this study is to evaluate the implementation of the protocol of sepsis in a university general hospital in Porto Alegre.

**Materials and methods:** Retrospective evaluation of protocols for sepsis in emergency in 2012.

**Results:** A total of 200 patients were enrolled in the protocol during the study period. The average age was 35 years (SD = 16.5), 51% of patients were male, the most frequent focus was respiratory 61%, and the second urinary with 14%. Clinical criteria for inclusion in the protocol that most prevailed were: axillary temperature and heart rate, with more than 95%. Altered axillary temperature was present in 98% of the sample. Of these cases, 86.5% (n = 173) of patients were discharged within 24 hours. Twenty-seven patients met criteria for hospitalization, 22% required the ICU. Around 75% (n = 20) of inpatients had no blood cultures collected before starting antibiotics. Only 7% mortality (n = 2).

**Conclusions:** The criteria for inclusion in the protocol are quite sensitive and the number of visits per month in the emergency exceeds 10,000. A total of 200 patients enrolled to the sepsis care protocol in a year, over 80% of these being discharged within 24 hours, suggests a low adherence to institutional protocol, especially in patients with septic shock, which is reinforced by the very low mortality compared with literature data. The evaluation of these data was essential to bring the knowledge that adherence to the protocol is still very low in our institution.

**P45**

**Septic shock by mechanical ventilation-associated pneumonia**

Hospital of Clinicals, Faculty of Medicine of Ribeirão Preto, University of São Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P45; doi:10.1186/cc12945
Background: A 69-year-old woman underwent elective surgical repair of an abdominal aortic aneurysm. Intraoperative lesions were intestinal and splenic, requiring performing segmental bowel resection and splenectomy. By hemodynamic instability the patient was maintained on mechanical ventilation in norepinephrine and was transferred to the ICU. After 3 days she had fever, tachycardia, hypotension and anuria, with output field had purulent secretion by the tracheal tube. Chest X-ray showed opacity in the right lung; cultures were collected and ceftazime initiated empirically for treatment of ventilator-associated pneumonia. Acinetobacter baumannii was isolated sensitive only to polymyxin-E in the sample of tracheal secretions. An exchange of antimicrobial therapy was made, but the patient developed refractory shock and died.

Materials and methods: We report the case of a patient with septic shock.

Results: Despite the upgrading of intensive therapies with the presence of increasingly prepared professionals and all of the technological and scientific developments that occurred in the last 10 years, sepsis remains a major challenge for contemporary medicine. Mortality rates may vary from 20 to 80%. Several factors contribute to this high mortality rate, such as the growing population of patients aged over 65 years with various chronic diseases, the most frequent use of invasive procedures, increased demand for immunocompromised patients and the development of nosocomial microorganism infections increasingly resistant to antimicrobial agents. Besides the pathophysiology, evidence substantiated that early intervention reduces mortality in severe sepsis and thus several ICUs have sought to improve the quality of clinical management of septic patients. In 2002, the Medical Society of Intensive American (SCCM) and European (ESICM) together with the International Sepsis Forum initiated the Surviving Sepsis Campaign (SSC). The SSC initiative was based on six strategies, including: implement surveillance sepsis; improve the early diagnosis and safety; establish protocols for treatment and early intervention; create programs continuing professional education; proposed therapy post-ICU; and develop global standards for intensive care.

Conclusions: The emergence of antimicrobial-resistant microorganisms is a growing problem worldwide and this complicates the choice of empirical antimicrobials and can compromise the evolutionary outcome of patients.

P46 Predictors of mortality in patients with severe sepsis admitted to an ICU
Fernanda Vilas Bôas Araújo1, Fábio Ferreira Amorim2, Adrieli Ramalho Santana3, Felipe Bozi Soares1, Bárbara Magalhães Menezes1, Jacqueline Lima de Souza1, Mariana Pinheiro Barbosa de Araújo2, Louise Cristina de Carvalho Santos2, Pedro Henrique Gomes Rocha1, Lucas Garcia de Souza4, Kátia Crys Moura Ogliari1, Pedro Nery Ferreira Júnior1, Aletheia Patrícia Pontes Amorim2, Rodrigo Santos Biondi1, Rubens Antônio Bento Ribeiro1

Critical Care 2013, 17(Suppl 4):P46; doi:10.1186/cc12946

Background: Severe sepsis is an important cause of morbidity and mortality for patients in ICUs [1]. Since instituting rapid treatment for patients with sepsis is critical, the need for reliable predictors of mortality to guide therapy is evident. This study attempts to identify the risk factors for mortality in patients admitted with severe sepsis to the ICU.

Materials and methods: Case-control study conducted in the ICU of Hospital Anchieta, Brasilia, DF, Brazil, during 5 months. Patients were divided into two groups: survivors group (SG) and nonsurvivors group (NSG).

Results: During the study, 38 patients were admitted with severe sepsis, with a mortality rate of 47% (n = 18). Upon admission, the patients in the NSG presented higher values of: SAPS3 score (82 ± 12 vs. 60 ± 14, P = 0.00), in-hospital stay (19 ± 21 vs. 99 ± 15 bpm, P = 0.00), serum lactate (2.4 ± 1.4 vs. 1.5 ± 0.9 mg/dl, P = 0.00), decreased level of consciousness (92% vs. 58%, P = 0.00), need for vasopressor (85% vs. 25%, P = 0.00), need for invasive mechanical ventilation (62% vs. 12%, P = 0.00) and previous cardiac arrest (15% vs. 0%, P = 0.00). The platelet count was lower in the NSG (119,000 ± 70,000 vs. 220,000 ± 103,000/mm3, P = 0.00). There was no significant difference between the groups regarding the following factors: age (65 ± 19 vs. 65 ± 19 years, P = 0.98), respiratory rate (29 ± 9 vs. 26 ± 7 rpm, P = 0.30), axillary temperature (36.9 ± 0.7 vs. 37.2 ± 1.8°C, P = 0.43), leukocyte count (17,500 ± 7,800 vs. 13,000 ± 6,000/mm3, P = 0.08), immunosuppression (38.5% vs. 12.5%, P = 0.07), and prior use of corticosteroids (23% vs. 25%, P = 0.90).

Conclusions: SAPS3 score, metastatic cancer, decreased level of consciousness, need for vasopressor, invasive mechanical ventilation and prior use of corticosteroids were significantly associated with mortality in severe sepsis for this sample of patients.

P47 Serum arterial lactate at the time of admission as a predictor of mortality in patients admitted with severe sepsis and septic shock to an ICU
Adrieli Ramalho Santana1, Fábio Ferreira Amorim1, Bárbara Magalhães Menezes1, Felipe Bozi Soares1, Fernanda Vilas Bôas Araújo2, Jacqueline Lima de Souza1, Mariana Pinheiro Barbosa de Araújo2, Louise Cristina de Carvalho Santos2, Pedro Henrique Gomes Rocha1, Osvaldo Gonçalves da Silva Neto1, Guilherme Menezes de Andrade Filho1, Pedro Nery Ferreira Júnior1, Aletheia Patrícia Pontes Amorim2, Rodrigo Santos Biondi1, Rubens Antônio Bento Ribeiro1
1Escola Superior de Ciências da Saúde, Brasilia, Brazil; 2Liga Acadêmica de Medicina Intensiva de Brasília, Brasilia, Brazil
Critical Care 2013, 17(Suppl 4):P47; doi:10.1186/cc12947

Background: Elevated serum arterial lactate levels are often associated with an imbalance between oxygen demand and delivery, which has a strong correlation with poorer outcomes in critically ill patients [1,2]. This study aims to evaluate serum arterial lactate as a predictor of mortality in critical patients admitted with severe sepsis and septic shock.

Materials and methods: Retrospective cohort study conducted in the ICU of Hospital Anchieta, Brasilia, DF, Brazil, during 3 years. For the first analysis, patients were divided into two groups: group with arterial lactate >2 mmol/l and group with low arterial lactate ≤2 mmol/l at the time of admission. For a second analysis, patients were divided into two groups: group with arterial lactate >3.3 mmol/l and group with arterial lactate ≤3.3 mmol/l at the time of admission.

Results: A total of 195 patients with sepsis were enrolled, 41% (n = 80) with septic shock. Mean age was 63 ± 22 years, ICU length of stay 9 ± 11 days, SAPS3 62 ± 16, and APACHE II 21 ± 9. ICU mortality in 4 days was 10.8% (n = 21), in 28 days was 12.2% (n = 24), and hospital mortality was 26.2% (n = 51). The nonsurvivor patients had higher lactate values (2.0 ± 1.4 vs. 1.3 ± 1.1, P = 0.00). Considering the arterial lactate cutoff value of 2.0 mmol/l, there was no difference between groups regarding ICU length of stay (10 ± 13 vs. 9 ± 2 days, P = 0.47), mortality in 4 days (12% vs. 10%, P = 0.83), mortality in 28 days (13% vs. 16%, P = 0.77), and hospital mortality (30% vs. 32%, P = 0.86). However, considering the lactate cutoff value of 3.3 mmol/l, the high lactate group had higher mortality in 4 days (27% vs. 9%, P = 0.04) and hospital mortality (67% vs. 23%, P = 0.00). There was no statistical significant difference regarding mortality in 28 days (27% vs. 11%, P = 0.08), and ICU length of stay (8 ± 7 vs. 8 ± 9 days, P = 0.59). The relative risk of hospital death in patients with arterial lactate >3.3 mmol/l was 2.93 (95% CI: 1.87 to 4.58). The specificity of arterial lactate >3.3 mmol/l for hospital mortality was 96.5% (95% CI: 92.1 to 98.5%), sensitivity was 19.6% (95% CI: 11.0 to 32.5%), and ROC curve for mortality was 0.634 (95% CI: 0.540 to 0.748).

Conclusions: In the patients admitted with severe sepsis and septic shock, the nonsurvivors had higher lactate values. Arterial lactate >2 mmol/l at the time of admission was not associated with mortality. Arterial lactate >3.3 mmol/l was associated with mortality in 4 days, and hospital mortality. Indeed, lactate >3.3 mmol/l had high specificity for hospital mortality.

Comparison of demographics and outcomes of patients with severe sepsis admitted to the ICU with or without septic shock
Barbara Magalhães Menezes, Fernanda Vilas Bôas Araujo, Fábio Ferreira Amorim, Adriell Ramalho Santana, Felipe Bozi Soares, Jacqueline Lima de Souza, Mariana Pinheiro Barbosa de Araújo, Louise Cristhine de Carvalho Santos, Pedro Henrique Gomes Rocha, Mateus Gonçalves Gomes, Osvaldo Gonçalves da Silva Neto, Pedro Nery Ferreira Júnior, Aletheia Patrícia Pontes Amorim, Rodrigo Santos Bioni, Rubens Antônio Bento Ribeiro

1Escola Superior de Ciências da Saúde, Brasília, Brazil; 2Liga Acadêmica de Medicina Intensiva de Brasília, Brasília, Brazil; 3Hospital Anchieta, Brasília, Brazil

Background: Severe sepsis and septic shock are common and are associated with substantial mortality and substantial consumption of healthcare resources [1]. Although the incidence of septic shock has steadily increased during the past several decades, the associated mortality rates have remained constant or have decreased only slightly [2]. This study aims to compare demographics and outcomes of patients admitted to the ICU with severe sepsis and with or without septic shock.

Materials and methods: The present study is a retrospective cohort conducted over a 3-year period in the ICU of Hospital Anchieta, Brasília, Brazil. Patients were divided into two groups: severe sepsis without septic shock (SW) and severe sepsis with septic shock (SS). The patients coming from other ICUs or transferred to other ICUs were excluded.

Results: A total of 198 patients with severe sepsis were enrolled in this study. Among them, 97 patients (49%) had septic shock. In this cohort, the mean age was 59 ± 16 years, the SAPS 3 score was 63 ± 17 and the APACHE II score was 21 ± 9. The mortality in four days was 12.6% (n = 25), in 28 days was 14.1% (n = 28) and the hospital mortality was 29.3% (n = 58). There was no difference between the groups regarding age (64 ± 20 vs. 59 ± 17, P = 0.08) and length of stay in the ICU (12 ± 1 vs. 11 ± 1, P = 0.51). The SS group presented higher SAPS3 (70 ± 17 vs. 57 ± 15, P = 0.00) and APACHE II (1 vs. 8 ± 9 ± 1, P = 0.00) scores. Patients in the SS group also had higher mortality in 4 days (18% vs. 8%, P = 0.04), in 28 days (20% vs. 9%, P = 0.03) and hospital mortality (37% vs. 22%, P = 0.02).

Conclusions: Patients admitted with septic shock had higher mortality than patients admitted with severe sepsis without septic shock, but there was no difference between the groups with respect to length of stay in the ICU.

Organ dysfunction and mortality in septic patients admitted to an ICU

1Escola Superior de Ciências da Saúde, Brasília, Brazil; 2Liga Acadêmica de Medicina Intensiva de Brasília, Brasília, Brazil; 3Hospital Regional de Samambaia, Brasília, Brazil

Background: Sequential Organ Failure Assessment (SOFA) is a largely used score in the evaluation of organ dysfunction/failure in septic patients [1]. Repeated scoring can also assess patient condition and disease development [2]. The present study aims to describe the association between SOFA score and the organ dysfunction components of this score with mortality in septic patients admitted to an ICU.

Materials and methods: Prospective study conducted on patients admitted to the ICU of Hospital Regional de Samambaia, Brasília, DF, Brazil, during 7 months. Patients were divided into two groups: survivors group (SG) and nonsurvivors group (NSG). Patients proceeding from or transferred to another ICUs were excluded.

Results: During the period of the study, 1,918 patients were admitted, 120 with septic shock (6.2%). For this sample, the mean age was 62 ± 20, SAPS3 was 71 ± 18, 55.8% were males, and the hospital mortality was 49% (n = 59). In the NSG group, there was a higher incidence of decreased level of consciousness (83.1% vs. 52.5%, P = 0.00), acute respiratory failure (96.6% vs. 83.6%, P = 0.03), hypoponpia (60.8% vs. 39.2%, P = 0.02), acidemia (77.4% vs. 50%, P = 0.01), need for invasive mechanical ventilation (83.1% vs. 45.9%, P = 0.00), and thrombocytopenia <60,000/mm³ (23.4% vs. 4.9%, P = 0.00). There was no difference between the groups regarding age (64 ± 21 vs. 61 ± 18, P = 0.37), PaO2/FiO2 ratio (174 ± 129 vs. 250 ± 236, P = 0.07), gender (47.5% vs. 63.9%, P = 0.037), incidence of acute renal injury (47.5% vs. 32.8%, P = 0.14), and arterial lactate (2.1 ± 1.1 vs. 1.8 ± 1.0, P = 0.13). The NSG group had greater SAPS3 score (82 ± 14 vs. 60 ± 15, P = 0.00). After logistic regression, only decreased level of consciousness (P = 0.00) and need for invasive mechanical ventilation (P = 0.01) were independently associated with hospital mortality.

Conclusions: In patients with septic shock, decreased level of consciousness and need for invasive mechanical ventilation were independently associated with hospital mortality.

Page 30 of 59
Results: One hundred and seven patients were enrolled. Mean age was 53 ± 20, APACHE II 14 ± 6, SAPS 3 52.9 ± 14.9 and SOFA 6.2 ± 3.3. ICU mortality was 34.6% (n = 37). The SOFA score was higher in nonsurvivors (7.4 ± 3.0 vs. 5.8 ± 3.4, P = 0.01), cardiovascular (2.0 ± 1.8 vs. 1.4 ± 1.6, P = 0.01) and kidney dysfunctions (0.7 ± 1.0 vs. 0.4 ± 0.9, P = 0.04) being higher in this group. There were no differences between the groups regarding coagulation (0.4 ± 0.8 vs. 0.4 ± 0.8, P = 0.59), liver (0.0 ± 0.3 vs. 0.0 ± 0.7, P = 0.65), respiratory (2.0 ± 1.2 vs. 1.6 ± 1.4, P = 0.87), and neurologic (2.2 ± 1.7 vs. 1.7 ± 1.6, P = 0.96) organ dysfunctions. The area under the ROC curve (Figure 1) for SOFA was 0.650 (95% CI 0.541 to 0.759). The components of the cardiovascular system, renal system, coagulation, liver, respiratory, and nervous systems had areas under the ROC curve of 0.612 (95% CI 0.501 to 0.732), 0.565 (95% CI 0.478 to 0.712), 0.484 (95% CI 0.369 to 0.600), 0.457 (95% CI 0.344 to 0.571), 0.580 (95% CI 0.469 to 0.691), and 0.582 (95% CI 0.465 to 0.699), respectively.

Conclusions: The SOFA score was moderately associated with ICU mortality. The scores for cardiovascular and renal impairment were individually associated with mortality.

SaO2/FiO2 ratio as risk stratification for patients with sepsis
Adriell Ramalho Santana1, Jaqueline Lima de Sousa1, Fábio Ferreira Amorim1, Bárbara Magalhães Menezes1, Fernanda Vilas Bôas Araújo1, Felipe Boz Soares1, Louise Cristhine de Carvalho Santos1, Mariana Pinheiro Barbosa de Araújo1, Pedro Henrique Gomes Rocha1, Pedro Nery Ferreira Júnior1, Alessandra Vasconcelos da Silva Paiva1, Gabriel Kanhouch2, Alethea Patrícia Pontes Amorim2, José Aires de Araújo Neto3, Edmilson Bastos de Moura2, Marcelo de Oliveira Maa2
1Escola Superior de Ciências da Saúde, Brasília, Brazil; 2Liga Acadêmica de Medicina Intensiva de Brasília, Brazil; 3Hospital Santa Luzia, Brasilia, Brazil
Critical Care 2013, 17(Suppl 4):P51; doi:10.1186/cc12951

Background: The PaO2/FiO2 ratio is a well-known parameter to assess respiratory dysfunction, used in Sequential Organ Failure Assessment (SOFA) [1]. This study aims to determine whether the SaO2/FiO2 ratio can be used in the assessment of respiratory impairment and as a predictor of ICU mortality in patients with sepsis and to evaluate its correlation with PaO2/FiO2.

Materials and methods: A retrospective cohort study conducted in the ICU of Hospital Santa Luzia, Brasilia, DF, Brazil, during 5 months. An arterial blood sample was collected at the time of admission. Patients with sepsis were divided into two groups: survivors group (SG) and nonsurvivors group (NSG). Correlation with SaO2/FiO2 and PaO2/FiO2 was evaluated with the Pearson correlation coefficient. Accuracy of SaO2/FiO2 and PaO2/FiO2 to predict ICU mortality was measured with the area under the receiver operating characteristic curve.

Results: A total of 118 patients with sepsis were enrolled. The mean age was 66 ± 21 years, SAPS3: 50 ± 14, APACHE II: 13 ± 8, PaO2/FiO2: 317...
(IQ 233 to 426) and SaO2/FiO2: 362 (IQ 247 to 453). ICU mortality was 17.8% (n = 21). The main sites of infections were respiratory (57%, n = 67), urinary (19%, n = 23) and cutaneous (8.5%, n = 10). Non-surviving patients had lower SaO2/FiO2 (258 vs. 366, P = 0.00) and PaO2/FiO2 (285 vs. 354, P = 0.04). PaO2/FiO2 and SaO2/FiO2 had a good correlation (r = 0.645, P = 0.00). The relative risk of death in patients with SaO2/FiO2 <400 was 1.81 (95% CI: 1.47 to 2.24), SaO2/FiO2 <300 was 2.5 (95% CI: 1.54 to 4.05), SaO2/FiO2 <200 was 2.45 (95% CI: 1.27 to 4.71). The sensitivity for ICU mortality of SaO2/FiO2 <300 was 28% and of SaO2/FiO2 <200 was 35%. The specificity for ICU mortality of SaO2/FiO2 <300 was 90% and of SaO2/FiO2 <200 was 86% (95% CI: 93.5 to 100.0%). The area under the ROC curve for SaO2/FiO2 was 0.776 (95% CI: 0.677 to 0.875) and for PaO2/FiO2 was 0.655 (95% CI: 0.507 to 0.804) (Figure 1).

Conclusions: A low SaO2/FiO2 was associated with mortality in this group of patients and had a good correlation with PaO2/FiO2. SaO2/FiO2 <300 showed high specificity for mortality. Further analysis is necessary to validate less invasive measures such as pulse oximetry saturation (SpO2/FiO2 ratio) in the assessment of patients with sepsis.

Figure 1 (abstract P51) ROC curve for SaO2/FiO2 and PaO2/FiO2.
mortality at 4 and 28 days. Accuracy of P/L to predict ICU mortality was measured with the area under the receiver operating characteristic curve. Results: In the present study, 195 patients were enrolled, 41% (n = 80) with septic shock. Their mean age was 62.8 ± 21.6 years, SAPS 3 was 62.1 ± 15.0, APACHE II was 20.6 ± 8.6, and length of stay in the ICU was 9 ± 11 days. Mortality at 4 days was 10.8% (n = 21) and at 28 days was 12.3% (n = 24). The groups P/L < 8 and P/L ≥ 8 did not present differences regarding age ([59 ± 20 vs. 65 ± 22, P = 0.07] and APACHE II ([22 ± 9 vs. 20 ± 9, P = 0.19]). The LPL group had higher SAPS3 (68 ± 18 vs. 59 ± 13, P = 0.00). The LPL was significantly associated with mortality in 4 days (18% vs. 7%, P = 0.02) and 28 days (19% vs. 9%, P = 0.03). The area under the ROC curve of P/L for mortality at day 4 was 0.628 (95% CI 0.498 to 0.757) and at day 28 was 0.613 (95% CI 0.489 to 0.736). Conclusions: P/L < 8 at admission was associated with higher mortality in 4 and 28 days in patients with sepsis.

Impact of sepsis on older and nonolder patients: clinical conditions and outcomes
Jaqueлина Lima de Souza1, Fábio Ferreira Amorim2, Adniell Ramalho Santana1, Felipe Bozi Soares1, Bárbara Magalhães Menezes1, Mariana Pinheiro Barbosa de Araújo1, Fernanda Vilas Bôas Araújo1, José Aires de Araújo Neto1, Edmilson Bastos de Moura3, Marcelo de Oliveira Maia3

Background: The increase of the older population, with higher incidence of co-morbidities and age-related decline in organic functions, suggests a need for better understanding the peculiarities of the process leading to adequate critical care in this group of patients [1,2]. This study aims to evaluate the individual components of SIRS criteria as predictors of mortality in patients admitted to an ICU with sepsis.

Materials and methods: A case-control study conducted in the ICU of Hospital Santa Luzia, Brasilia, DF, Brazil, during 4 months. Patients were divided into two groups: survivors group (SG) and nonsurvivors group (NSG). The accuracy of individual components of SIRS criteria as predictors of mortality was measured with the area under the receiver operating characteristic (ROC) curve.

Results: A total of 76 patients were enrolled, 10.5% (n = 8) with septic shock. Age was 70 ± 18 years, SAPS3: 52.9 ± 13.9, APACHE II: 15.5 ± 8.8. The ICU length of stay was 9 ± 10 days. ICU mortality was 21% (n = 16). The most prevalent sites of infections were respiratory (57.9%, n = 44), followed by urinary (25%, n = 19) and cutaneous (6.6%, n = 5). The incidence of tachycardia was the only parameter higher in the NSG (25.0% vs. 17.5%, P = 0.42) or leukocytosis or leucopenia (20.9% vs. 21.2%, P = 0.97) between the groups. The relative risk of death in patients with tachycardia was 4.13 (95% CI: 1.46 to 11.63). Tachycardia also had the larger area under the ROC curve: 0.708 (95% CI: 0.566 to 0.850), versus 0.442 (95% CI: 0.287 to 0.597) for fever/hypothermia, 0.556 (95% CI: 0.397 to 0.715) for tachypnea, and 0.498 (95% CI: 0.338 to 0.658) for leukocytosis/leucopenia.

Conclusions: For this sample, tachycardia was the only SIRS component associated with ICU mortality in patients admitted with sepsis.

SaO2-SvO2 difference for risk stratification of patients with sepsis and septic shock
Fábio Ferreira Amorim1, Adniell Ramalho Santana1, Jaqueline Lima de Souza1, Felipe Bozi Soares1, Bárbara Magalhães Menezes1, Mariana Pinheiro Barbosa de Araújo1, Fernanda Vilas Bôas Araújo1, Louise Cristhine de Carvalho Santos1, Pedro Henrique Gomes Rocha1, Lucila de Jesus Almeida1, Thais Almeida Rodrigues1, Pedro Nery Ferreira Júnior1, Alethea Patricia Pontes Amorim2, José Aires de Araújo Neto1, Edmilson Bastos de Moura3, Marcelo de Oliveira Maia3

Background: The ACCP/SCCM consensus conference definitions for sepsis are used worldwide [1]. However, consensus definitions do not adequately reflect the intricacies of sepsis and can overestimate the diagnosis due to their high sensitivity. Moreover, the consensus criteria do not allow the staging or the prediction of sepsis outcome [2]. This study aims to evaluate the individual components of SIRS criteria as predictors of mortality in patients admitted to an ICU with sepsis.

Materials and methods: A retrospective cohort study conducted in the ICU of Hospital Santa Luzia, Brasilia, DF, Brazil, during 6 months. Patients diagnosed with sepsis were divided into two groups: older, defined as age ≥65 years, and nonolder, with age <65, for the analysis of the outcomes.

Results: A total of 130 patients were enrolled, 11.5% (n = 15) with septic shock. Mean age was 64 ± 22 years, ICU length of stay 9 ± 10 days. Mortality was 9 ± 11 days. Mortality at 4 days was 10.8% (95% CI 0.498 to 0.757) and at day 28 was 0.613 (95% CI 0.489 to 0.736). Conclusions: P/L < 8 at admission was associated with higher mortality in 4 and 28 days in patients with sepsis.
Background: Assessment and monitoring of hemodynamics is a cornerstone in critically ill patients as hemodynamic alteration may become life-threatening in a few minutes [1,2]. This study aimed to determine whether the SaO₂-SvO₂ difference could be used as a risk stratification for patients with sepsis and septic shock.

Materials and methods: A retrospective cohort study conducted in the ICU of Hospital Santa Luzia, Brasilia, DF, Brazil, during 6 months. An arterial blood sample was collected at admission. Patients with sepsis were divided in two groups: survivors group (SG) and nonsurvivors group (NSG).

The accuracy of SaO₂-SvO₂ difference to predict ICU mortality was measured with the area under the receiver operating characteristic curve.

Results: A total of 101 patients with sepsis were enrolled, 11.5% (n = 15) with septic shock. Age was 66 ± 21 years, SAPS3: 37 ± 17, APACHE II: 14 ± 8, PaO₂/FiO₂: 342 ± 142 and SaO₂/FiO₂: 347 ± 109. ICU mortality was 18% (n = 23). The main sites of infections were respiratory (56.5%, n = 74), urinary (19%, n = 25) and cutaneous (7.6%, n = 10). Nonsurvivor patients had higher SaO₂-SvO₂ difference (26 ± 9 vs. 19 ± 9, P = 0.03). In the group of patients with septic shock, SaO₂-SvO₂ difference was also higher in nonsurvivors (29 ± 3 vs. 10 ± 2, P = 0.02). All patients with septic shock who died had SaO₂-SvO₂ difference greater than 25%. The SaO₂-SvO₂ difference area under ROC curve was 0.714 (95% CI 0.534 to 0.894).

Conclusions: A higher SaO₂-SvO₂ difference is associated with mortality in patients with sepsis, especially in patients with septic shock.

Sepsis and multiple organ dysfunction in burn

Sabrina F Henrich1, Tatiana H Rich, Iuri C Wawrzeńck, Rafael B Moraes, Karen F Prado, Marcos C Boniatti, Denise Matter, Lília Biacon, Geissano Custódio, Roberto Ritter

Unidade de Terapia Intensiva, Hospital de Clínicas de Porto Alegre, Brazil

Critical Care 2013, 17(Suppl 4):P57; doi:10.1186/cc12957

Background: Advances in the treatment of burns have reduced mortality rates and improved quality of life of victims. However, the most frequent complication is infection [1]. Thermal injury over 20% of the body surface area may lead to conditions similar to SIRS, as in septic shock. Beyond the extent of body surface area burned, which causes structural changes in skin coverage, other factors lead to infectious complications in burned patients: immunosuppression resulting from thermal injury, the possibility of gastrointestinal bacterial translocation, prolonged hospitalization, the use of devices and surgical procedures related to the burned areas [2,3]. C-reactive protein (CRP) is a known marker of infection and sepsis in patients admitted to the ICU.

Materials and methods: CRP was measured in a cohort of 18 critically ill mechanically ventilated victims of a fire disaster in the city of Santa Maria, Brazil, on 27 January 2013, admitted to the ICU of the Hospital de Clínicas de Porto Alegre. The patients were divided into groups according to CPR levels, group 1 (CPR ≤ 190 mg/l) and group 2 (CPR > 190 mg/l), and the Mann-Whitney test was performed to compare groups according to mortality, length of ICU and hospital stay, presence of sepsis and SOFA score on days 1, 3 and 7.

Results: Six patients were male and the mean age was 23.1 ± 4.5 years. No differences were detected when patients were compared according to mortality (group 1: 0% vs. group 2: 11.1%; P = 0.48), length of ICU stay (group 1: 11 ± 8 days vs. group 2: 17.2 ± 9.7 days; P = 0.237) or length of hospital stay (group 1: 16.4 ± 8.5 days vs. group 2: 20.6 ± 10.2 days; P = 0.408). CPR levels were not associated with the development of sepsis (group 1: 50% vs. group 2: 80%; P = 0.321). The SOFA score was not significantly different between groups on day 1 and day 3 (day 1 - group 1: 4.6 ± 2 vs. group 2: 4.5 ± 2.7; P = 0.740; day 3 - group 1: 3.2 ± 2.7 vs. group 2: 5.8 ± 4.2; P = 0.203). However, the SOFA score was significantly higher on day 7 in group 2 (group 1: 3 ± 0.7 vs. group 2: 5.8 ± 1.9; P = 0.017).

Conclusions: CRP was not a good marker of sepsis and multiple organ dysfunction in this cohort of burned patients, possible due to the intense inflammatory response associated with burns.

Clinical performance of a point-of-care assay for measurement of presepsin in patients with bacteremia

Yasu Fukui1, Yoshikazu Okamura2

1Department of Gastroenterological Surgery, Kochi Health Sciences Center, Kochi, Japan. 2Research and Development Division, Yachiyo R&D Department, Mitsubishi Chemical Medience Corporation, Tokyo, Japan

Critical Care 2013, 17(Suppl 4):P58; doi:10.1186/cc12958

Background: The soluble CD14 subtype (sCD14-ST: renamed presepsin), which is approximately 13 kDa, has been identified as a protein whose levels increase specifically in the blood of sepsis patients. In this study, we evaluated the clinical performance of a point-of-care assay for measurement of presepsin in admitted sepsis patients.

Materials and methods: We obtained 43 cases with blood culture test-positive from patients admitted to our hospital and compared presepsin levels with procalcitonin (PCT), CRP and white blood cell count.

Results: Positive ratios of presepsin levels of patients with Gram-negative bacterial infection, Gram-positive bacterial infection and fungal infection
were higher than those of PCT. When 43 cases were divided into four groups (sepsis, severe sepsis, septic shock and infection groups), presepsin levels were only significantly different between sepsis/infection group and severe sepsis group (P < 0.05). Presepsin levels reflected the blood culture test and sepsis severity more than other biomarkers.

**Conclusion:** This assay has sufficient clinical performance in patients admitted to the hospital in addition to the emergency room and ICU.

**P60**

Does the ICU experience predict psychological symptoms in relatives of patients with severe sepsis and end-of-life decisions?

Christiane Hartog1,2, Daniel Schwarzkopf3, Helga Skupin1, Björn Kabisch1, Ruediger Pfeifer3, Albrecht Guenther4, Konrad Reinhart1,2

1 Department of Anaesthesiology and Intensive Care Medicine, Jena University Hospital, Jena, Germany; 2 Center for Sepsis Control & Care, Jena University Hospital, Jena, Germany; 3 Department of Internal Medicine I, Jena University Hospital, Jena, Germany; 4 Department of Neurology, Jena University Hospital, Jena, Germany

Critical Care 2013, 17(Suppl 4):P60; doi:10.1186/cc12959

**Background:** Severe sepsis is the main cause of death in the ICU. Relatives are at risk for post-traumatic stress disorder (PTSD) or anxiety for PTSD, 48% for anxiety and 33% for depression. Overall satisfaction (74%), spouse (42%) or child (42%), median age was 57 years. Seventy-seven percent acted as proxies. After 90 days, 51% relatives were at risk for PTSD, 48% for anxiety and 33% for depression. Overall satisfaction with the ICU experience was high. Relatives’ satisfaction with medical care and communication in general as well as specifically in the end-of-life context, and decision-making. Three multiple linear regression models were calculated to predict anxiety, depression and post-traumatic stress each.

**Materials and methods:** Prospective observational study in four ICUs of one university hospital, including all patients with severe sepsis and end-of-life-decisions. At 90 days, the main relative was interviewed with the ICU experience, including medical care and communication in general as well as specifically in the end-of-life context, and decision-making. Three multiple linear regression models were calculated to predict anxiety, depression and post-traumatic stress each.

**Results:** Eighty-four relatives were included. They were mostly female (74%), spouse (42%) or child (42%), median age was 57 years. Seventy-seven percent acted as proxies. After 90 days, 51% relatives were at risk for PTSD, 48% for anxiety and 33% for depression. Overall satisfaction with the ICU experience was high. Relatives’ satisfaction with medical care and communication in general predicted lower anxiety (P = 0.025).

**Conclusions:** Relatives of patients with sepsis have a high psychological burden. Improving communication between ICU staff and relatives may reduce their symptoms of anxiety.

**Acknowledgements:** Funded partly by the German Ministry of Education and Research (grant number 01 E0 1002). This investigation was part of a study to improve quality of end-of-life care in the ICU (trial registration NCT01247792).

Quality assurance in severe sepsis: an individualised audit/feedback system results in substantial improvements in sepsis care at a large UK teaching hospital

Mark Simmonds1, Esme Blyth, Marc Chikhani, Jaimie Coleman, Vivienne Weston, Tim Hills

Sepsis Action Group, Nottingham University Hospitals NHS Trust, Nottingham, UK

Critical Care 2013, 17(Suppl 4):P61; doi:10.1186/cc12960

**Background:** Severe sepsis has a high mortality and high healthcare costs. Rapid recognition and treatment can save lives but requires a coordinated response [1]. Hospital-wide audits in 2005 and 2010 showed significant deficiencies when compared with international guidelines, with 35% of cases receiving antibiotics in <1 hour and only 25% receiving basic pre-ICU interventions in a timely manner. By time-lining our response to severe sepsis, we identified system and process failures [2]. Some system improvements (for example, providing first-line antibiotics in acute areas) were straightforward to tackle, but sepsis care remained reliant on individual clinician response. Equally, whilst dissemination of organisation-level audit data raised the profile of sepsis, it appeared that individual clinicians did not view it as ‘their problem’. It is recognised that individualised feedback can improve care, as pride and the competitive nature of healthcare workers drives improvement. This is especially true when adherence to recommended practice is low [3]. We tried to change behaviour by creating a rapid response audit/feedback mechanism that informed clinicians of their own response to the severely septic patient, from which they could learn and improve.

**Materials and methods:** Patients admitted to any critical care unit (58 beds, four units, two sites) with a primary admission diagnosis of sepsis were included. A prospective observational study over 6 months was performed in a single large UK teaching hospital (58 beds, four units, two sites) with a primary admission diagnosis of sepsis. The study was based on the CONSORT guidelines (Figure 1). A rapid response audit system was developed to improve sepsis care. Data was collected prospectively on 155 patients and was fed back as monthly feedback. The feedback was based on the multi-level framework (Figure 1). The multi-level framework was designed to show the relative contribution of individual clinician and system failures. Each component was described as an outcome measure and a target time. The target time was defined as the time needed to complete each component of the multi-level framework (Table 1). The target time was defined as the time needed to complete each component of the multi-level framework (Table 1).

Figure 1 (abstract P61) Example report.
infection were screened for severe sepsis. The pre-ICU care of patients who met the criteria was then audited against the Surviving Sepsis Guidelines [1]. Time zero was defined as when the criteria for severe sepsis were first met. Information on timings of key interventions (such as doctor review and request for critical care escalation) was also gathered. An individualised traffic-light report was then generated and emailed to the patient’s consultant and other stakeholders such as junior doctors or nurses involved in the patient’s care (Figure 1). We aimed to report cases back within 7 days of arrival to ensure the patient story was fresh in the clinician’s mind. A cumulative report is generated monthly to track organisation-wide performance.

Results: Since November 2011 we have provided feedback on over 300 severe sepsis cases. Antibiotic administration in <1 hour has risen from 35% to 75% (Figure 2), and pre-ICU bundle compliance has risen from 25% to 70% (Figure 3). Since November 2012 all sepsis cases in our critical care units have been audited (30 to 35 cases/month).

Conclusions: Individualised feedback on sepsis care has led to substantial improvements in guideline compliance.

LD50 values of ISS or NISS from the Chinese Trauma Data Bank and their application in predicting post-trauma sepsis
Huaping Liang*, He Jin, Zheng Liu, Ya Xiao
Department 1, Research Institute of Surgery, Daping Hospital, The Third Military Medical University, Chongqing, People’s Republic of China

Background: To introduce the LD50 values of ISS or NISS from the Chinese Trauma Data Bank, and to compare the roles of some formulae including LD50 values in predicting the onset of post-trauma sepsis.

Materials and methods: Data of 6,542 patients (aged ≥16) from the Chinese Trauma Data Bank were analyzed to obtain the LD50 values of ISS or NISS using probit regression. A total of 908 trauma patients (aged ≥16) admitted to Daping Hospital of Chongqing from January 2011 until June 2012 (908 patients) was used to validate the model.

Results: The LD50 values of ISS or NISS were examined for 6,542 patients (aged ≥16) from the Chinese Trauma Data Bank. The LD50 value of ISS (151) and NISS (36) were obtained using probit regression. In the model of LD50 values of ISS, the area under the ROC curve was 0.961 (95% CI 0.934-0.988). In the model of LD50 values of NISS, the area under the ROC curve was 0.970 (95% CI 0.943-0.997). The LD50 values of ISS and NISS were validated in 908 trauma patients (aged ≥16) admitted to Daping Hospital of Chongqing from January 2011 until June 2012 (908 patients). The area under the ROC curve for LD50 values of ISS and NISS was 0.962 (95% CI 0.929-0.995) and 0.961 (95% CI 0.914-0.998), respectively.
2013 were enrolled. Discrimination and calibration of the ISS, NISS, SIRS score (the first 3 days post trauma), ISS/LD50ISS, NISS/LD50ISS, SIRS score, NISS/SIRS score, ISS/LD50ISS SIRS score, NISS/LD50ISS SIRS score, and NISS/LD50ISS+SIRS score in predicting post-trauma sepsis were compared using receiver operator characteristic (ROC) curves and Hosmer-Lemeshow statistics.

**Results:** The LD50 values of ISS for age 16 to 44, 45 to 64, and ≥65 were 55, 49, and 33, respectively (for males: 54, 50, and 31; for females: 60, 47, and 39). The LD50 values of NISS for age 16 to 44, 45 to 64, and ≥65 were 62, 56 and 43, respectively (for males: 62, 56, and 42; for females: 65, 53, and 48). The predicting capability of ISS/LD50ISS+SIRS score and NISS/LD50NISS+SIRS score were equivalent (area under the ROC curve = 0.932 versus 0.932) and both showed better discrimination than others in predicting post-trauma sepsis. For ISS/LD50ISS+SIRS score, the cutoff value of ROC curve was 2.2128, with a positive predictive value of 65.86%, a negative predictive value of 95.95%, a specificity of 87.13%, a sensitivity of 87.11%, a positive likelihood ratio of 6.76, a negative likelihood ratio of 0.15, a Youden index of 0.7424, and an accuracy of 87.11%. For NISS/LD50NISS+SIRS score, the cutoff value of ROC curve was 2.2128, with a positive predictive value of 65.86%, a negative predictive value of 95.95%, a specificity of 87.13%, a sensitivity of 87.11%, a positive likelihood ratio of 6.76, a negative likelihood ratio of 0.15, a Youden index of 0.7481, and an accuracy of 87.11%.

**Conclusions:** This study calculates for the first time the LD50 values of ISS or NISS from Chinese trauma patients. The novel and simple formulae ISS/LD50ISS+SIRS score and NISS/LD50NISS+SIRS score are then set up to predict the incidence of sepsis following traumatic injury, which perform better at predicting capability than ISS, NISS, SIRS score and other formulae including LD50 values of ISS or NISS.

### P63 Treatment of sepsis: a systematic review of its main concepts

**Jéssica Samanta,** Magna Angelica Alves, Edwin Radingo Paiva Borges, Beatriz Murata Mutakami

Faculty of Nursing, Hospital Israelita Albert Einstein, Sao Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P63; doi:10.1186/cc12962

**Background:** Sepsis is a major challenge in medicine, its high incidence, mortality and high costs making this syndrome the leading cause of mortality in ICUs, and is considered a health problem in a worldwide extension that affects millions of people and results in high morbidity and mortality. It is believed there are 18 million annually reported cases, and of every four people diagnosed one is victimized by sepsis [1-3]. The aim of this study was to identify the main aspects in the treatment of sepsis in the last 10 years.

**Materials and methods:** A quantitative, descriptive and cross-sectional, literature study, concerning the main aspects in the treatment of sepsis. A semi-structured instrument developed by the authors was used to collect data to categorize the studies obtained. After collection, an electronic spreadsheet was generated, and data were analyzed using descriptive statistics.

**Results:** Ten studies with a central theme focused on the treatment of sepsis were used. Seventy percent of these studies were between the years 2008 and 2011. Fifty percent of the articles mentioned that the early approach of the infectious agent is very important for successful treatment, while 60% reported that the control of the infectious focus is one of the main alternatives. Fifty percent of the studies also reported an infusion of antibiotics in accordance with the infectious focus as essential to the treatment of sepsis, and 80% reported the use of activated protein C as an indicator for diagnosis septic patients. It is observed that most studies seek early detection of the infection and early antibiotic administration, which reinforces the need for optimization of processes for sepsis. Early diagnosis of sepsis is a key element of the sepsis protocol proposed by the Latin American Institute of Sepsis (ILAS).

**Conclusions:** The present study therefore concludes that for effective treatment of sepsis an early approach right after diagnosis of the disease is indispensable. Likewise, the treatment of sepsis primarily seeks to control the infectious focus using specific antibiotics. Also, the use of activated protein C may be a good alternative in the diagnosis of this pathology and a good indicator for controlling this disease.

### P64 Epidemiology of sepsis in a university hospital in Rio de Janeiro

Sergio da Cunha1, Mario CA Perez2, Elisabette N Ferreira3, Julio CD Correa1, Viviane S Silva4, Eliane PP Assumpção5, Luan F Almeida6, Catherine C Valdez7, Jéssica R Oliveira8, Thereza CF Camello9, Paulo V Damascos10

1Faculdade de Ciências Médicas, Universidade do Estado do Rio de Janeiro, Brazil; 2Hospital Universitário Pedro Ernesto, Universidade do Estado do Rio de Janeiro, Brazil; 3Escola de Medicina e Cirurgia, Universidade Federal do Estado do Rio de Janeiro, Brazil

Critical Care 2013, 17(Suppl 4):P64; doi:10.1186/cc12963

**Background:** Severe sepsis and septic shock are challenges in critical medicine care and there are few epidemiologic studies in public university hospitals in Brazil.

**Materials and methods:** A prospective study was performed to determine the epidemiology of the sepsis in hospitalized patients in our institution (600-bed tertiary teaching urban hospital) from September 2012 to May 2013. The criteria for sepsis definition were obtained from the 2013 guidelines [1]. Clinical and epidemiological data were collected from patients’ records. A univariate, bivariate and multivariate analyses were performed.

**Results:** In total, we analyzed 103 patients with severe sepsis and septic shock during the period of study. The frequency of male gender was 55.8% and a median age of 62 years was observed in the patients. The median acute physiology and chronic health disease classification system II (APACHE II) score estimated was 21.1 and a community origin of sepsis was present in 53.4% of them with a mortality rate of 61.3%. Yet in 57 (64.0%) patients with healthcare-associated sepsis, the mortality rate was 63.1% and the risk of death was higher for this group (odds ratio (OR) = 5.54; 95% confidence interval (CI) = 2.19 to 14.0; P < 0.05). In the entire group, 53.4% had septic shock and 60.1% entered the vasopressor protocol. In relation to the source of infection, the top three were: pulmonary (51.4%), abdominal (14.5%) and urinary (12.6%). We observed the greatest risk of death in the group with pulmonary infection (OR = 3.08; 95% CI = 1.1 to 8.5; P = 0.03). The prevalence of positive blood cultures was 32.1% and 23 microorganisms were identified, these being 65.2% Gram-negative bacilli (Klebsiella pneumoniae (21.7%), Escherichia coli (17.3%)), 21.2% Gram-positive cocci and 13.6% fungi. Lethality in sepsis episodes was associated independently with the delay in starting antibiotic therapy (more than 6 hours: OR = 2.94; 95% CI = 1.05 to 8.02; P = 0.04), inappropriate plasmatic volume expansion use (less than 20 ml/kg; OR = 2.84; 95% CI = 1.07 to 7.5; P = 0.03) and pulmonary source of sepsis (OR = 3.08; 95% CI = 1.1 to 8.5; P = 0.03). The use of corticosteroids seemed to increase the mortality rate, but in the multivariate analysis this association failed to reach statistical significance (OR = 2.2; 95% CI = 0.08 to 6.5, P = 0.1).

**Conclusions:** Enterobacteriaceae and pulmonary sepsis were the main factors responsible for triggering sepsis. Fast and aggressive fluid therapy and early adequate antibiotics are mandatory to change the lethality in severe sepsis and septic shock. Further studies evaluating the effect of therapy with corticosteroids should be assessed.

Burden of mortality related to sepsis in Brazil from 2002 to 2011
Luciano CP Azevedo1,2,3*, Leandro U Taniguchi1,2, ... Kernel density estimates
Critical Care 2013, Volume 17 Suppl 4
http://ccforum.com/supplements/17/S4
Page 38 of 59
< 0.05.
chi-square test for trend. Rate changes were considered significant when
the standard. Trends of mortality rates over time were explored with the
Geography and Statistics with the 2010 census age-stratified population as
denominators population estimates provided by the Brazilian Institute of
estimated. In addition, age, gender, ethnicity, and outcome variables were
derelated to their temporal changes is available. Few population-based sources of
data have been used to investigate the burden of sepsis-associated mortality on a national level. We investigated the epidemiology of sepsis
deaths in Brazil from 2002 to 2011 using secondary data from the
Brazilian Mortality Information System (Sistema de Informações de Mortalidade (SIM)).

Materials and methods: A retrospective descriptive study using data
reported to the Brazilian SIM for the years 2002 to 2011. SIM is an
electronic, case-based mortality registry that derives its information almost entirely from death certificates. Sepsis-associated deaths from 2002 to
2011 were identified based on International Classification of Diseases 10th
Revision codes listed on the underlying and on the contributing causes-of-
death. Population-based sepsis-associated mortality rates and trends were
estimated. In addition, age, gender, ethnicity, and outcome variables were
assessed. Considering the cases of sepsis identified during the study
period, annual population-based mortality rates were calculated using as
denominators population estimates provided by the Brazilian Institute of
Geography and Statistics with the 2010 census age-stratified population as
the standard. Trends of mortality rates over time were explored with the
chi-square test for trend. Rate changes were considered significant when
P < 0.05.

Results: The total number of deaths recorded in SIM increased over the
decade. In 2002 there were 982,294 deaths reported and in 2010 this
number was 1,133,761. The number of sepsis deaths increased from
95,972 (9.8%) to 186,712 (16.5%). The average age of sepsis-associated
deaths progressively increased from 60.2 years in 2002 to 2003 to 67.1
years in 2010 to 2011. During the same period the average age of all
deaths increased from 57.8 years to 62.7 years. White individuals were
more frequent (60.4%), as compared with mixed race (24.4%) and blacks
(6.6%). A substantial part of sepsis deaths occurred in the hospital (94.8%). The age-adjusted rate of sepsis-associated mortality increased from
69.5 deaths per 100,000 to 97.8 deaths per 100,000 from 2002 to
2010 (P < 0.001).

Conclusions: Between 2002 and 2011, the contribution of sepsis to all
cause mortality increased significantly in Brazil. Moreover, age-adjusted mortality by sepsis also augmented in the last decade. These numbers
confirm the importance of sepsis as a significant healthcare issue in Brazil
as well as the need for adequate strategies of early recognition and
treatment.

P66
Microbiological profile in an ICU in 1 year
Joel Passos1, Paulo Pires, Sérgio Curvelo, Decio Netto, Bruna Passos,
Larissa Peixoto, Bruno D’Avila
Unimed Costa do Sol, Macaé, Brazil
Critical Care 2013, 17(Suppl 4):P66; doi:10.1186/cc12965

Background: Critical patients requiring prolonged intensive care are more
at risk of being colonized by germs acquired in an ICU and present
infections. The factors that contribute to the high rate of infection and
mortality in ICUs are possibly associated with the severity of the
underlying disease, invasive procedures, the long period of hospitalization
and use of antibiotics, especially the expanded spectrum, so that there are
multidrug-resistant bacteria, which complicates therapy. Approximately 5%
of patients admitted to ICUs will acquire a nosocomial infection, resulting
in increased length of hospitalization, around 5 to 10 days, and will be
considered a consequence of healthcare in 30% of cases. Diagnostic or
therapeutic interventions provide breakdown of the mechanical barrier of the
skin and mucus assigned to invasive, skin lesions caused by
development, trauma or by removing the skin secondary to burns or
debridement. In addition to the mechanical factors that disrupt the natural
barriers of defense, there are others that are inherent in clinical conditions
of patients and promote the acquisition of infections in the hospital
environment; the immune ability is compromised because the natural
defense mechanisms are altered by the very nature base or as a result of
therapeutic interventions. The rate of infection is high among intensive
care patients, especially respiratory infections. Pseudomonas aeruginosa
was the prevalent bacteria in our ICU. That is why the prevalence of
infection acquired in the ICU is high and suggests that preventive
measures are important to reduce the occurrence of infection in critical
patients.

Materials and methods: Retrospective study, analyzing culture results for
1 year in a ICU with 10 beds in the northern of state of Rio de
Janeiro. We considered cultures of urine, blood, cerebrospinal fluid,
tracheal aspirate, nasal swabs and catheter tip, and detected the most
prevalent microorganisms in our ICU.

Results: We analyzed 453 cultures, 178 (39.29%) were positive for some
germs, 240 (52.98%) were negative and 35 (7.72%) had impaired analysis.
Among the cultures were performed 152 blood cultures, 38 (25%)
positive and 114 (75%) negative, 96 urine cultures, 36 (52.17%) positive
and 60 (47.83) negative, 31 samples of tracheal secretions, 20 (64.51%)
positive and 11 negative (35.49%), 141 nasal swabs, 71 (50.35%) positive
and 70 negative (49.65%), and 27 cultures from the catheter tip, six
(22.22%) positive and 21 (77.78%) negative. Among the positive blood
cultures assayed as being prevalent was 31.57% with P. aeruginosa,
the second Staphylococcus aureus and Proteus mirabilis with the same number of
specimens, 15.78%. Among the 36 positive urine cultures, Candida
albicans was the prevalent with 22.22%, second place was 13.88%
Escherichia coli and P. mirabilis was third with 11.11%. The cultures were
tracheal P. aeruginosa as the most prevalent in half of the cases (50%), and
secondly C. albicans and Acinetobacter baumannii at 10%. Among the
cultures of nasal swab taken on admission of patients, the prevalent
germs was P. aeruginosa with 26.76%, in second place with 12.67% was
P. mirabilis and third with the same number of cases were A. baumannii
and Serratia marcescens, 11.26%. Among the catheter tip cultures,
P. aeruginosa was prevalent with 40%, and P. mirabilis second with 20%.
There no was positive cerebrospinal fluid culture in the period.

Conclusions: This study contributes to the knowledge of local resistance
rates, which is one of the basic steps for the establishment of individualized
strategies regarding the use of antimicrobials.

Acknowledgements: We are thankful to the Director, Laboratory and
Committee of the Hospital Infection Control from Hospital Unimed Costa
do Sol, whose contributions have made this study possible.

Hourly and accurate severe sepsis classification using kernel density
estimates
Jacquelyn D Parente1*, Geoffrey M Shaw2, Dominic S Lee3, J Geoffrey Chase1
1Centre for Bioengineering, Department of Mechanical Engineering,
University of Canterbury, Christchurch, New Zealand; 2Department of
Intensive Care, Christchurch Hospital, Christchurch, New Zealand;
3Department of Mathematics and Statistics, University of Canterbury,
Christchurch, New Zealand
Critical Care 2013, 17(Suppl 4):P67; doi:10.1186/cc12966

Background: Sepsis score classifications increase conditionally with
concurrent systemic inflammatory response syndrome (SIRS) score,
Sequential Organ Failure Assessment score, and clinical intervention.
However, hierarchical criteria fail to accurately classify sepsis when related
physiological manifestations are resolved, while the underlying infection
remains.

Materials and methods: To enable hour-to-hour sepsis classification, we
examined the diagnostic performance of a continuous sepsis score. We
developed a model that categorized the severity of sepsis using a
logistic kernel density estimate that scores independently, rather than hierarchically. Kernel density estimates
were used to classify severe sepsis (including septic shock) of 1,690 hours over 6,550 total hours. Optimal diagnostic performance from the receiver operating characteristic (ROC) curve was determined for in-sample, out-of-sample, and overall estimates. 

Results: The severe sepsis biomarker achieved 86% sensitivity (81 to 94%), 85% specificity (80 to 95%), 0.93 (0.88 to 0.99) area under the ROC curve, 8.2 (4.0 to 19.0) positive likelihood ratio, 0.17 (0.06 to 0.23) negative likelihood ratio, 68% (58 to 87%) positive predictive value, 94% (92 to 98%) negative predictive value, and a diagnostic odds ratio of 116 (17 to 306) at an optimal probability cutoff value of 0.25.

Conclusions: This clinical biomarker can thus be readily assessed at the bedside to yield a non-invasive and continuous estimate of the probability of severe sepsis. The results show high accuracy as a potential severe sepsis diagnostic and monitoring response to sepsis interventions in real time.

P68
Potential anti-inflammatory role of 2-chloroadenosine treatment during acute lung inflammation in BALB/c mice suffering from Klebsiella pneumoniae BSS55-induced acute lung infection

Vijay Kumar1, Kusum Harjai, Sanjay Chhibber
Department of Microbiology, Panjab University, Chandigarh, India

Background: Acute lung inflammation (ALI) is a life-threatening pathology and can develop during the course of several clinical conditions such as pneumonia, acid aspiration or sepsis. Adenosine plays a significant role in controlling acute inflammation via binding to A2A receptors on inflammatory cells, that is, neutrophils or macrophages. The present study was designed to evaluate the anti-inflammatory and immunomodulatory effects of 2-chloroadenosine (2-CADO), alone or in combination with amoxicillin/clavulanic acid (AMC), in Klebsiella pneumoniae BSS55-induced acute lung infection in mice.

Materials and methods: Acute lung infection in mice was induced by directly instilling the selected dose (10⁴ colony-forming units/ml) of bacteria intranasally. Histopathological examination of the lungs was performed to reveal neutrophil infiltration into the lung alveoli. In addition to the major proinflammatory cytokines TNFα and IL-1α, levels of the anti-inflammatory cytokine IL-10 were also determined by ELISA.

Results: Intranasal instillation of bacteria caused profound neutrophil infiltration into the lung alveoli as well as a significant increase in the levels of proinflammatory mediators (that is, TNFα and IL-1α). However, intravenous administration of 2-CADO 10 μg/kg/day, alone or in combination with an antibiotic (that is, AMC 20 μg/ml/day i.p. 1 day after establishment of infection), significantly decreased neutrophil infiltration into the lung alveoli. A significant decrease in TNFα and IL-1α along with elevation of IL-10 levels in the lung homogenate of mice with acute lung infection was observed upon treatment with 2-CADO alone, with no significant decrease in bacterial counts. Moreover in combination with AMC, 2-CADO exhibited its immunomodulatory action in acute lung infection and prevented ALI observed during acute bacterial pulmonary infection, whilst an antibacterial action was exhibited by AMC.

Conclusions: 2-CADO proved a potent immunomodulatory agent during acute Gram-negative bacteria-induced ALI and exhibited its anti-inflammatory and immunomodulatory potential even in the presence of antibiotics. Thus, it has a potential to be used as an adjunct immunomodulatory agent during acute inflammatory conditions like ALI or sepsis.

P69
Beneficial effects of vigorous fluid resuscitation therapy varied depending on the time of onset and the sepsis stage in rats: preliminary study

Ana MA Liberatori¹, IVan HJ Koh²
¹Department of Pediatric, Federal University of São Paulo, SP, Brazil; ²Department of Surgery, Federal University of São Paulo, SP, Brazil

Background: Fluid replacement has been a usually recommended maneuver in sepsis; however, growing clinical controversies in the management of critically ill patients with severe sepsis have questioned its benefit. Herein, we evaluated the effect of a rapid hyperhydration (HH) therapy in varying stages of sepsis.

Materials and methods: Wistar-FPM rats, weighing 200 to 250 g, were submitted to two sepsis models: S8 group, submitted to 2 ml Escherichia coli 10⁷ CFU/ml intravenous (i.v.) inoculation, LD50, or S9 group, with E. coli 10⁷ CFU/ml inoculation, LD50. Both groups were treated with HH (30 ml/kg of Ringer lactate i.v., in 20 minutes) in the early (E30 minute) and late (L6 hour) phases of sepsis. The mortality was followed up to 30 days (n = 6/group) and the splanchic microcirculation was monitored by sidestream dark field imaging (SDF) video microscopy at 6-hour and 24-hour periods (n = 3/group/period).

Results: The HH at the E30 minute phase of S8 improved the survival rate from 40% to 90%, and L6 hour phase HH promoted an 80% survival rate. Besides, the survival rate in S9 (LD50), with E30 minute HH, improved the survival rate from 20% to 50%. However, it was less effective as compared with the E6H phase HH, which resulted in an expressive survival rate (from 20% to 70%). These intriguing results suggested that there is an interdependent and time-dependent pathophysiology feature within the host response based on sepsis severity stage and a rapid high-volume reposition. The SDF analysis in control sepsis groups (S8 and S9), without fluid therapy, showed a broadly distributed microcirculation dysfunction in the liver lobules and kidney tubules at 6 hours after sepsis challenge, and such findings were similar between groups, but after 24 hours the survivors showed an improved microcirculation hemodynamic pattern and it was more evident in the S8 group. The survivals of the S8 E30 minute treated group showed less injury at 6 hours and 24 hours as compared with nontreated and S8 L6 hour treated animals. In S9 treated groups, both showed a partial repair at 24 hours post sepsis.

Conclusions: The hyperfluid therapy given rapidly in both early and late phases in sepsis and severe sepsis states showed that its beneficial effect was more or less effective dependent on the phase and sepsis intensity; however, the more prominent survival rates were seen at the early phase of sepsis (S8) and at the later phase of severe sepsis (S9). The underlying pathophysiology evolved in these paradoxical conditions needs to be better elucidated.

Possible variables related to paradoxical findings between PCR and hemoculture assays in rat experimental sepsis

Marcello R da Silva¹, Marcos M Casteleiro², Darcy José de Sá Filho², Ivan HJ Koh¹
¹Department of Pediatrics, Federal University of São Paulo, Brazil; ²Department of Pediatrics, Lusíada University Center, Lisbon, Portugal;

Background: A positive blood culture (BC) is considered the gold standard method for the sepsis diagnosis, although its sensibility is low (10 to 30%) which demands a better diagnostic tool to limit broad-spectrum antibiotic use in the majority of patients without culture-based sepsis diagnosis. Besides, after microbial invasion, they can remain live, dead or fragmented in the bloodstream, thus limiting BC efficiency. Herein we evaluated the PCR diagnostic efficacy under live, dead and bacterial DNA contents in the bloodstream.

Materials and methods: Wistar rats were distributed in three groups (n = 20/group) based on live, dead and DNA inoculations. The LPS+DNA group (1 mg/kg LPS injection plus 4 hours later DNA injection, n = 10) was assigned for DNA detection under an induced inflammatory state. Live, Dead and extracted DNA forms of Pseudomonas aeruginosa (ATCC 27853) relative to 2 ml of 10⁷ colony-forming units/ml were injected into the circulation. Blood samples were collected after 20 minutes and 6 hours (n = 10/group/period), and were submitted to nested PCR assay using general and specific primers. BC was performed with 200 μl and 3,000 μl only in the Live group.

Conclusions: This clinical biomarker can thus be readily assessed at the bedside to yield a non-invasive and continuous estimate of the probability of severe sepsis. The results show high accuracy as a potential severe sepsis diagnostic and monitoring response to sepsis interventions in real time.
Results: In the Live group, at 20 minutes the sensitivity was 100% by both BC and PCR and at 6 hours the sensitivity was 60% (with 200 μl) and 90% (with 1,000 μl) in BC, and 80% in PCR sampled with 50 μl blood volume. In the Dead group, the PCR sensitivity was 90% at 20 minutes and 50% at 6 hours. In the DNA group, the sensitivity remained at 50% independent of time. The inflamed condition did not change PCR sensitivity. Overall data showed that in both techniques the sensitivity dropped with time. In the BC assay the positivity was dependent on sampled blood volume, and in the PCR it was related to live or dead condition. These findings suggest that the live bacteria remain for a short period of time in the bloodstream while DNA can last for longer periods.

Conclusions: Considering that PCR is performed with 40x less blood compared with a habitual BC, PCR can be an assay of choice when BC is negative and in conjunction in a live bacteria circulating condition. Besides, the PCR assay with specific primers can be a useful method for sepsis diagnosis in specific bacterial surge events in the ICU, thus improving antibiotic usage potentials.

Involvement of ghrelin in the neonatal exposure to lipopolysaccharide and thermoregulation during endotoxemia in adulthood
Mayara Andrade Ferrai1, Marcelo Eduardo Batallhão, Evelin Capellari Cârnio
School of Nursing of Ribeirão Preto - University of São Paulo (USP), Ribeirão Preto, Brazil

Critical Care 2013, 17(Suppl 4):P71; doi:10.1186/cc12970

Background: Prior exposure to infection, particularly during the neonatal phase, contributes to individual differences in susceptibility to disease during adult life. Animal neonates undergoing lipopolysaccharide administration (LPS) react differently to the front endotoxemia in adulthood. Ghrelin, a peptide hormone originally found in the stomach, has effects on the modulation of the inflammatory response. Specific receptors are found for ghrelin on neutrophils, macrophages and lymphocytes and their activation by ghrelin inhibits the production of several inflammatory cytokines, including nitric oxide (NO). Therefore, our objective is to evaluate the role of ghrelin in the attenuation of fever during endotoxemia in adulthood induced by neonatal exposure to LPS.

Materials and methods: The study was conducted using rats in the pregnancy phase. After the birth of pups (day 0 of the experiment) we selected only male rats. All animals were weaned at 21 days and at 14 days of age received neonatal administration of LPS 100 μg/kg intraperitoneally (i.p.). Subsequently they were separate in cages until they reached 8 to 12 weeks of age for the experiment (by endotoxemia in adult administration of 10 mg/kg LPS i.p.). To determine the body temperature, the animals were anesthetized and a capsule inserted into the peritoneal cavity biotelemetry. Body temperature was measured for a period of 6 hours after induction of endotoxemia. To verify the effect of ghrelin and ghrelin antagonist on body temperature during endotoxemia, ghrelin was administered 0.1 mg/kg ghrelin antagonist or 50 nmol/kg i.p. concomitant administration of LPS. After decapitation, blood samples were collected and centrifuged to separate the plasma. The plasma was stored at -70°C for subsequent determination of NO.

Results: In our preliminary data we observed no significant difference in fever-induced endotoxemia in animals subjected to LPS administration in the neonatal period, when compared with their respective controls.

Conclusions: These data do not corroborate the findings of the literature and we believe it is due to the fact that the animals used until now have had prior exposure to pathogens. So in our next experiments we will use experimental animals that are specific pathogen free.

 Interruption of the intestinal immune route to the systemic circulation associated with early hyperthermia minimized splanchic microcirculation damage and improved sepsis survival
Fernando M Dulcin1, Ana MA Liberatore2, Bianca C Zychar1, Ivan HJ Koh1
1Department of Surgery, Federal University of São Paulo, Brazil; 2Department of Pediatrics, Federal University of São Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P72; doi:10.1186/cc12971

Background: Considering that the communication of the intestinal immunity with the systemic bloodstream can be a relevant adjuvant factor in the amplification of the host systemic inflammatory response and subsequent multiple organ dysfunction in sepsis, we aimed to evaluate the effect of the obstruction of the mesenteric lymph duct (OMLD) associated with massive fluid therapy in the early phase of sepsis and severe sepsis models.

Materials and methods: Adult Wistar-EPF rats were submitted to 10^8 (S8) or 10^9 (S9) CFU/ml Escherichia coli inoculum intravenously (i.v.) (ΔΔP = 26 hours), and were treated with hyperhydration (HH) with or without previous OMLD (n = 5/group). Control group were naive animals (IN) and animals submitted to HH or sepsis only. The mortality of groups was followed up to 30 days after experiments and microcirculation monitoring was observed at 6 hours post sepsis induction by videomicroscopy (sidestream darkfield imaging (SDF)).

Results: The effect of OMLD + HH reduced significantly the sepsis mortality rate: 58 (60% to 14.5%) and 59 (80% to 60%). Besides, the liver and kidney microcirculatory features were better preserved as compared with untreated sepsis groups under video-microscopy (SDF) monitoring.

Conclusions: These preliminary findings showed that both HH and OMLD have a potential therapeutic application in sepsis by minimizing the splanchic organ’s microcirculation dysfunction.

Effect of sepsis challenge in chronic inflammation state on mortality and long-term pathological findings in rats
Roberto Tussi-Junior1, Eduardo LS Bastos2, Ana MCRPF Martins2, Rodrigo B Souza1, Ana MA Liberatore1, José CF Vieira1, Ivan HJ Koh1
1Department of Surgery, Federal University of São Paulo, Brazil; 2Institute of Biology of São Paulo State, São Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P73; doi:10.1186/cc12972

Background: Recent studies from our laboratory showed that animals subjected to 50% shortening of the small intestine developed bacterial translocation unleashed chronically. Bacterial translocation has shown the effect of exacerbation of systemic inflammatory response by crosstalk between intestinal and systemic immune response. In this sense, the aim of this study was to evaluate whether a septic challenge in the state of chronic inflammation resulting from the shortening of the small bowel can modify the mortality outcome and trigger organ alterations in the long term.

Materials and methods: Wistar-EPF rats were submitted to 50% small intestine shortening (IS group, n = 20) or sham intestinal anastomosis (IA group, n = 20), and after 4 months were submitted to sepsis challenge with 2 ml 10^8 CFU/ml Escherichia coli i.v. The mortality was observed up to 30 days and the survivors of both groups were killed after 6 months for histological analysis. The other 10 animals were killed after 4 months of intestinal shortening in order to determine the histological pattern related to the bowel shortening effect.

Results: The mortality rate after sepsis was 80% in the IS group and 35% in the IA group. The bowel shortening without sepsis challenge showed hepatic mild steatosis with inflammation similar to acute hepatitis, vascular congestion and focal necrosis. The distal ileum showed shortening and broadening of villus, focal cryptic necrosis and mild macrophages and eosinophil infiltration in the lamina propria. In the IS group was seen a generalized steatosis and vascular congestion in the liver; alveolar atelectasis, BAL hyperplasia, a large number of macrophages, mast cells, foam cells, lymphocytes, eosinophil and plasmocyte infiltration and alveolar edema, plus vascular congestion and sclerosis in the lung; villus atrophic necrosis, intense inflammatory cell infiltration and vascular congestion in the lamina propria of the ileum; and the kidney with tubular necrosis, tubular obstruction, vascular congestion with interstitium hemorrhage and tubular hyaline material deposition. In the IA group was seen moderate liver steatosis, intestinal lamina propria cellular infiltrations, glomerulonephritis, kidney tubular edema, parenchymal hemorrhage and...
Bowman capsule thickness. However, the alterations were less compared with the IS group.

Conclusions: The chronic inflammatory state, in combination with sepsis, might be an important aggravating factor related to sepsis morbidity and mortality by promoting an increasing organ dysfunction in the long term.

Cholecystokinin inhibits inducible nitric oxide synthase expression in lipopolysaccharide-stimulated macrophages
Evelin C Carlini1,2, Jussi G S Branco1, Rafael S Saia1
1Escola de Enfermagem de Ribeirão Preto - USP, Brazil; 2Faculdade de Odontologia de Ribeirão Preto - USP, Brazil; 3Faculdade de Medicina de Ribeirão Preto - USP, Brazil
Critical Care 2013, 17(Suppl 4):P74; doi:10.1186/cc12974

Background: Cholecystokinin (CCK) receptors are expressed in macrophages and are upregulated by inflammatory stimulus. In vitro and in vivo studies have demonstrated the ability of CCK to decrease the production of various proinflammatory cytokines. This study investigates the role of CCK on iNOS expression in lipopolysaccharide (LPS)-activated peritoneal macrophages, as well as the intracellular signaling pathways involved in affecting iNOS synthesis.

Materials and methods: Experimental procedures were approved by the Comitê de Ética em Experimentação Animal - FMRP (protocol number 152/2009). Thioglicate-celicited macrophages were obtained by peritoneal lavage and cultured in RPMI 1640 medium, 10% fetal bovine serum and antibiotics. Nuclear p65, CAMP and iNOS levels were determined using ELISA kits, CCK receptors and IFN-γ receptor complexes were evaluated through Western Blot and nuclear factor of the Giess票据. Data were compared by one-way ANOVA and significant differences obtained using the Tukey multiple variances post hoc test.

Results: CCK reduced NO production attenuating iNOS mRNA expression (15.49 ± 10.80 vs. 11.16 ± 0.23 AU; P < 0.05) and protein formation. Furthermore, CCK inhibited the NF-κB pathway reducing IκB degradation and minor p65-dependent translocation to the nucleus (54.78 ± 84.57 vs. 90.42 ± 9.13%, P < 0.05). Moreover, CCK restored the intracellular CAMP content activating the cAMP-protein kinase A (PKA) pathway, which resulted in a negative modulatory role on iNOS expression and nitrite production. In peritoneal macrophages, the CCK-1R expression was predominant and upregulated by LPS (0.61 ± 0.08 vs. 0.30 ± 0.09 AU; P < 0.05). The pharmacological studies confirmed that CCK-1R subtype is the major receptor responsible for the biological effects of CCK.

Conclusions: These data suggest an anti-inflammatory role for the peptide CCK in modulating iNOS-derived NO synthesis, possibly controlling the macrophage hyper-activation through NF-κB, cAMP-PKA and CCK-1R pathways.

CD11b and TLR4 in human neutrophil priming by endotoxins from Escherichia coli
Isabella Prokhorenko1, Dimitry Kabanov, Svetlana Zubova, Sergay Grachev
Institute of Basic Biological Problems, Pushchino, Moscow Region, Russia
Critical Care 2013, 17(Suppl 4):P75; doi:10.1186/cc12974

Background: The interaction of endotoxins (lipopolysaccharides (LPS)) from Gram-negative bacteria with peripheral blood mononuclear cells leads to the assembly of a receptor cluster composed of mCD14, CD11b/CD18, TLR4, CD16A and CD36 [1,2]. It is well known that the main signal transducing receptor complex is TLR4-MD-2 while mCD14 is involved in the recognition of S or R endotoxin’s glycoforms [3,4]. A growing body of evidence indicates that the CD11b/CD18 receptor plays the significant role in the endotoxin signaling machinery because it can influence TLR4-mediated cell activation [5]. So, using mAbs, we carried out experiments to elucidate the influence of CD11b inhibition on neutrophil priming by endotoxins for N-formyl-methionyl-leucyl-phenylalanine (fMLP)-induced respiratory burst.

Materials and methods: Human neutrophils were isolated from heparinized blood of healthy volunteers by standard procedure and incubated with or without anti-TLR4 mAbs (HTA125, IgG2a) or anti-CD11b mAbs (clone 44, IgG1) or isotypic immunoglobulin controls, respectively, for 30 minutes before stimulation with S-LPS or Re-LPS from Escherichia coli O55: B5 or JM103, respectively. The cells (2 x 10⁵), 2% of autologous serum, taurocholine and its receptor complex. J Immunol 2005, 175:3940-3945.

Introduction: Attention has been paid in recent years to studies showing immune cell death mechanisms during the course of sepsis in response to proinflammatory and anti-inflammatory mediators that are involved in its pathophysiology. Taurine (Tau) is an abundant amino acid in blood and spleen lymphocytes from septic rats submitted to sepsis Dhebora Mzenga Dall’igna1,2, Jaqueline Maffeizoli da Luz2,3, Francieli Vuolo2, Fábio Klamt1, Felipe Dal Pizzol1
1Instituto Nacional de Ciência e Tecnologia Translacional em Medicina, Unidade Acadêmica de Ciências da Saúde, Universidade do Extremo Sul Catarinense, Criciúma, SC, Brazil; 2Instituto de Ciências Básicas da Saúde, Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil
Critical Care 2013, 17(Suppl 4):P76; doi:10.1186/cc12975

Background: Taurine (Tau) decreases cell viability and cytokine production in blood and spleen lymphocytes from septic rats submitted to sepsis. The role of taurine in the pathophysiology of sepsis is still not clear, but it is believed that it could have a protective effect against the damages induced by the sepsis. The aim of the present study was to evaluate the effect of taurine on the viability and cytokine production in lymphocytes from septic rats.

Materials and methods: Adult male rats were divided in two groups: control and Taurine groups that were killed 24 or 120 hours after sepsis induction to isolate lymphocytes from the blood and spleen. Lymphocytes (>95.0% purity determined by differentiation with Giemsa staining) were cultured and isolated by the Ficoll density gradient centrifugation method. Then, lymphocytes were incubated with or without taurine (500 μM) for 24 or 120 hours. Cell viability was assessed using the trypan blue exclusion test. Cytokine production was evaluated by ELISA for TNFα, IFNγ, IL-6, IL-17A, IL-23 and IL-10. Results were analyzed by one-way ANOVA followed by Tukey post-hoc test.

Results: Taurine treatment significantly increased cell viability in lymphocytes from blood and spleen compared to the control group. Taurine also significantly decreased the production of TNFα, IFNγ and IL-17A in lymphocytes from both blood and spleen, while the production of IL-23 was not affected. The production of IL-6 and IL-10 was not significantly different between the taurine and control groups.

Conclusions: Taurine treatment significantly increased cell viability and decreased the production of pro-inflammatory cytokines in lymphocytes from blood and spleen of septic rats. These findings suggest that taurine could be a potential therapeutic agent in sepsis.
for 24 hours at a concentration of $1 \times 10^6$ cells/ml and activated by 2 mg/ml concanavalin A. After 24 hours, Tau and TauCl were added at concentrations of 0.1, 0.2, 0.3, 0.4 and 0.5 mM for 1 hour. After this time, cells were incubated with MTT (500 μg/ml) for 3 hours to evaluate cell viability and supernatants were used to determine cytokine concentrations.

**Results:** Tau-treated cells exhibited better viability than those treated with TauCl, in both time and organs. TauCl, in a time and dose-dependent ratio, decreased cytokines secretion when compared with untreated cells. See Figures 1 to 7.

**Conclusion:** These findings show a possible impairment in lymphocyte function promoted by TauCl, correlated with immunosuppression and cell death characteristic of the late stages of sepsis.

Background: Sepsis is a clinical condition resulting from the excessive inflammatory response of the host against an infectious agent and is associated with high morbidity and mortality in patients in ICUs. In sepsis the brain can be targeted, associated with mental damage and decline, impaired attention, disorientation, delirium and coma. It has been seen that the permeability of the blood-brain barrier (BBB) is associated with septic encephalopathy, allowing cell infiltration and increased oxidative stress. Accordingly, such events can be potentiated through the involvement of molecules that when activated perpetuate the inflammatory response and the breaking of the BBB, and it is possible to postulate that the CD40 molecule may be involved by being under increased expression in microglia in inflammatory events occurring systemically. The aim of this study therefore is to evaluate the role of CD40 in the breakdown of the BBB, cell infiltration and oxidative damage in the brain of rats with sepsis.

Materials and methods: Male Wistar rats were subjected to cecal ligation and puncture (CLP) to induce sepsis. The animals (n = 10) were...
Background: Endothelial dysfunction is a key step in endoxemia-derived sepsis syndrome pathogenesis. It is well accepted that the bacterial endoxin lipo polysaccharide (LPS) induces endothelial cell (EC) dysfunction through immune system overactivation [1–3]. However, LPS can also affect ECs in the absence of participation by immune cells [4–6]. Although interactions between LPS and ECs evoke endothelial death, a significant portion of ECs are resistant to LPS challenge [6–8]. However, the mechanism that confers endothelial resistance to LPS is not known. Considering that LPS-resistant ECs exhibit a fibroblast-like morphology, suggesting that these ECs enter in a fibrotic program in response to LPS, our aim was to investigate whether LPS induces endothelial fibrosis and explore the underlying mechanism.

Materials and methods: We used two different models: primary ECs, and intact blood vessels (IBV). Both preparations were freshly obtained from umbilical cord veins from normal pregnancies, after patients’ informed consent. The investigation conforms with the principles outlined in the Declaration of Helsinki. The Commission of Bioethics and Biosafety of Universidad Andres Bello approved all experimental protocols. Once the preparation was established they were cultured with or without LPS as a model of endotoxia. ECs were exposed to 20 mg/ml LPS for 72 hours, while IBV was challenged to 20 mg/ml LPS on the inside for 48 hours. 

Results: Our results show that in the most effective dose of 100 ng/kg anti-CD40 showed a decrease in the breakdown of the BBB, MPO, nitrite/nitrate concentration and TBARS. A dose of 1 ng/kg was effective only in the reduction of nitrite/nitrate concentration and 10 ng/kg was not effective in TBARS and carbonyl. Western blotting analysis showed increased expression of CD40 and CD40L in CLP animals when compared with sham.

Conclusions: Modulation of the levels of CD40 may represent a potential therapeutic target in sepsis.

Impaired calcium mobilization in vascular smooth muscle of rats in septic shock

Sandra Crestani*, Jose Eduardo da Silva Santos, Jamil Asreuy
Department of Pharmacology, UFSC, Florianópolis, SC, Brazil

Background: Calcium activity is essential to vascular smooth muscle contraction. Although it is well established that arteries from rats in septic shock present hyporesponsiveness to vasoconstrictor drugs, the role of calcium redistribution in this contractile dysfunction is far less investigated. We hypothesized that during septic shock calcium dynamics is changed and may have a role in the vascular dysfunction in sepsis.

Materials and methods: Female Wistar rats (3 months old) were anesthetized by oxygen-isoflurane (3%) inhalation and subjected to cecal ligation and puncture surgery (CLP). Immediately after and every 12 hours rats received physiological saline solution (PBS 30 ml/kg, subcutaneously) and tramadol (5 mg/kg, subcutaneously). After 6 hours (CLP-6) or 24 hours (CLP-24) rats were killed, the aorta was harvested and cut in rings, the endothelium was removed and rings were mounted in baths. Rings were exposed to KCl 120 mM and phenylephrine (PE 1 μM). Aorta rings were subjected to single concentrations of PE (1 μM) or caffeine (20 mM) in Ca2+-free solution, in the presence or absence of thapsigargin.

Results: Maximal contraction (E_max) induced by KCl or PE was reduced, especially in the CLP-24 group. Similarly, CaCl2-induced contraction was reduced (60%) in the CLP-24 group. Thapsigargin (sarcoplasmatic calcium reuptake blocker) and DTNB (sulphydryl oxidase) reduced the contraction elicited by CaCl2 in septic rings, but without effect in control rings. PE-induced contraction in calcium-free solution was significantly reduced in CLP-24 rings (E_max 1.6 ± 0.4 g control vs. 0.3 ± 0.1 g CLP-24 rings). Thapsigargin did not change the hyporesponsiveness to PE but PTIO (nitric oxide scavenger) restored it partially. Caffeine-induced contraction in Ca2+-free solution was reduced in CLP-24 rings (0.2 ± 0.06 g control vs. 0.03 ± 0.01 g in CLP-24). Thapsigargin or PTIO restored the contraction induced by caffeine.

Conclusions: These data suggest that in septic shock calcium sequestration is strongly impaired. Although preliminary, our results suggest that calcium channel nitrosylation and calcium reuptake may be reasons for the vascular hyporesponsiveness of septic shock.

Increased sympathetic tone contributes to cardiovascular dysfunction in sepsis
Ana Maria Favero1*, Regina Sordi1, Geisson Nardi2, Jamil Asreuy1
1Department of Pharmacology, Universidade Federal de Santa Catarina, Florianópolis, Brazil; 2Department of Biological Sciences and Health, Universidade do Oeste de Santa Catarina, Joaçaba, Brazil

Background: The cardiovascular dysfunction of sepsis/septic shock is characterized by hypotension, tachycardia/bradycardia, endothelial dysfunction and hyporesponsiveness to vasoconstrictors. Hypotension and low tissue perfusion trigger an increase in sympathetic tone probably as an attempt to restore blood pressure to normal levels. The persistently higher sympathetic stimulation may lead to the exhaustion of the capacity of vascular response and thus create a vicious circle contributing to vascular hyporesponsiveness and higher adrenergic stimulation. In addition, in septic shock patients, increased arterial levels of norepinephrine (NE) were significantly associated with mortality. The aim of this work was to evaluate the vascular response to an adrenergic agonist during severe sepsis and the effects of the early inhibition of sympathetic tone in sepsis-induced cardiovascular dysfunction.

Materials and methods: Sepsis was induced by cecal ligation and puncture (CLP) surgery in female Wistar rats. Septic animals and controls (CT) were treated with the ganglionic blockers pentolinium (PENT; 5 mg/kg, s.c.) or hexamethonium (HEX, 15 mg/kg, s.c.) or vehicle (saline) 1 hour after surgery. The vascular response to the administration of NE was assessed 6 hours after CLP surgery.

Results: Both CLP 24 and 48 hours groups presented thrombocytopenia (>40% reduction), lymphopenia, hyperglycemia, hyperlipidemia and leukopenia (P < 0.05), a clear indication of severe sepsis. However, only CLP 48 hour animals displayed refractory hypotension (MAP = 59 mmHg, vs. 78 mmHg in CT; P < 0.05) in spite of volume resuscitation. The highest doses of norepinephrine and dobutamine increased the MAP to 133.8 ± 8.1 and 97.8 ± 3.1 mmHg in CT, and to 120 ± 6.7 and 77.3 ± 4.4 mmHg in CLP 48 hour animals, respectively. The heart rate was significantly increased by norepinephrine and dobutamine in control, but not in CLP 48 hour animals. In addition, the basal values of both dP/dtmax and dP/dtmin, as well as after 1 nmol/kg dobutamine, were reduced in CLP 48 hour animals.

Conclusions: Using a pressure-volume catheter in a closed-chest approach we demonstrated that, in spite of the ability to increase blood pressure, the chronotropic effects of norepinephrine and dobutamine are reduced at 48 hours after CLP in rats subjected to CLP. In addition, all doses of norepinephrine, but only by the highest doses of dobutamine, improved systolic and diastolic function in these animals.

Reference
CLP 6 hours 21.9 ± 3.1; CLP 6 hours + HEX 52.6 ± 7.0; CLP 6 hours + PENT 54.1 ± 3.0; CLP 24 hours + PENT 64.4 ± 7.8 mmHg; P < 0.05 compared with control group). The early ganglionic blockade with PENT decreased the mortality observed after 96 hours. 

Conclusions: Our data indicate that increased sympathetic tone in sepsis contributes, at least in part, to the development of hypotension, hyporesponsiveness to vasoactive agents and mortality. Blockade of increased sympathetic tone thus may be considered as an adjuvant therapy for the treatment of septic cardiovascular dysfunction.

Vascular smooth muscle cell activation depends on NOS-1-derived NO and consequent peroxynitrite generation

Karim Schiechowitsch1, Regina de Sardi1, João Alfredo de Moraes2, Christina Barja-Fidalgo1, Jamil Assreuy1
1Department of Pharmacology, UFSC, Florianópolis, SC, Brazil; 2Department of Pharmacology, UERJ, Rio de Janeiro, RJ, Brazil

Critical Care 2013, 17(Suppl 4):P82; doi:10.1186/cc12981

Background: Low levels of nitric oxide (NO) play a key role in vascular tonus maintenance. Previous results from our laboratory show that hypotension and mortality during sepsis are prevented by the early administration of NOS-1 inhibitors. The aim of this study was thus to investigate the role of NOS-1 and NOS-3-derived NO and of other reactive oxygen species (ROS) in smooth muscle cell activation. 

Materials and methods: Smooth muscle cell line of rat aorta (A7r5) was used. Control cells and NOS-1 or NOS-3 silenced cells (siNOS-1 and siNOS-3, respectively) were stimulated with LPS 1 μg/ml and IFN 200 U/ml (LPS/IFN). NO and ROS production was assessed with fluorescent probes. NO content was evaluated by western blot and NOS-2 activity was indirectly measured by Griess reaction. Further, control cells were treated for 30 minutes with a NO scavenger (c-PTIO), a NOS inhibitor (7-NI) or a NADPH oxidase inhibitor (DPI) before stimulation. Immunofluorescence was used to evaluate protein nitration and NF-κB nuclear translocation. To confirm the role of peroxynitrite in cell activation, control cells were stimulated with a sub-effective amount of LPS/IFN together with a NO donor and a superoxide anion generator and treated with a NOS-2 inhibitor 4 hours after stimulation. Griess reaction was performed 48 hours after. Statistical comparisons were performed by two-way ANOVA followed by the Bonferroni test. 

Results: A7r5 control cells stimulated with LPS/IFN presented a rapid increase in intracellular NO and ROS content. These increases were prevented by c-PTIO, 7-NI and DPI, as well as in siNOS-1 and siNOS-3 cells. NOS-2 was only expressed after cell stimulation. Control cells incubated with c-PTIO or 7-NI and stimulated with LPS/IFN presented a diminished NOS-2 expression and activity. Only in siNOS-1 cells was NOS-2 expression and activity also reduced. Nuclear translocation of NF-κB and positive nitrotyrosine reaction were reduced in c-PTIO or 7-NI treated groups. Sub-effective concentrations of LPS/IFN did not induce significant nitrite production. However, when sub-effective LPS/IFN was associated with the production of low concentrations of peroxynitrite, nitrite accumulation was as high as in cells stimulated with activating concentrations of LPS/IFN. 

Conclusions: We show for the first time the importance of NOS-1-derived NO and peroxynitrite for smooth muscle cell activation. Cell stimulation with LPS/IFN causes an early NOS-1-derived NO pulse and a ROS pulse that forms peroxynitrite. The interplay between these species seems to be key events for NF-κB nuclear translocation and NOS-2 expression.

Estradiol cypionate modulates immunological response during sepsis

Luz E da Silva, Angélica M Stabile, Marcel E Batallão, Evelin C Camilo
College of Nursing at Ribeirão Preto, São Paulo, Brazil

Critical Care 2013, 17(Suppl 4):P83; doi:10.1186/cc12982

Background: Sepsis and its common complication septic shock are generally induced by the action of lipopolysaccharide (LPS) and characterized by peripheral arteriolar vasodilatation that results in hypotension and inadequate tissue perfusion. During sepsis, secretion occurs of large amounts of inflammatory mediators such as nitric oxide (NO), interleukin 1 (IL-1) and TNFα that will modulate the inflammatory response. One significant finding in clinics is that men and women respond differently to sepsis, with better prognosis related to women [1]. 

Materials and methods: Male and female (ovariectomized and sham surgery) rats were injected intraperitoneally (i.p.) for three consecutive days with ECP 40 μg/kg or vehicle. On the third day, after ECP injection, rats receive i.p. injection of 10 mg/kg bacterial LPS or saline solution. Plasma was collected 2, 4 and 6 hours after LPS for NO and cytokine measurements. 

Results: Administration of LPS increased the NO plasma concentration in males and females (2, 4 and 6 hours). ECP pretreatment decreased the NO concentration in sham females at 4 and 6 hours; conversely, it increased nitrate levels in ovariectomized and in males at 4 and 6 hours. IL-1 plasma concentration was increased in the three groups after LPS administration at 2 and 4 hours and in Sham at 6 hours; ECP pretreatment decreased IL-1 plasma concentration in all groups at 2 hours. LPS administration also increased TNFα plasma concentration at 2, 4 and 6 hours in the three groups; ECP pretreatment inhibited the increase of TNFα at 2 hours in three groups. 

Conclusions: Our results indicate that estradiol may have proinflammatory or anti-inflammatory actions depending on the gender and the mediator evaluated; this balance in mediator secretion may be protective and explain in part the better outcomes of woman during sepsis.

Sulphhydryl oxidation restores alpha-adrenergic vascular response and improves survival in septic rats

Patrícia de Oliveira Benedet, Gustavo Campos Ramos, Ana Maria Favero, Jamil Assreuy
Department of Pharmacology, Universidade Federal de Santa Catarina, Florianópolis, Brazil

Critical Care 2013, 17(Suppl 4):P84; doi:10.1186/cc12983

Background: The profound decrease in vasomotor tone accompanied by hyporesponsiveness to vasoconstrictors is an important contributor to morbidity and mortality in septic shock. Overproduction of nitric oxide (NO) has been shown to play a relevant role in septic shock vascular dysfunction. One of the mechanisms whereby NO exerts some of its effects is the reaction with thiols of cysteine residues in a process called S-nitrosylation, producing S-nitrosothiols. The aim of the present study is to show that modification in S-nitrosylation has an important impact in sepsis-induced vascular dysfunction and mortality.

Materials and methods: Wistar female rats were anesthetized and submitted to cecal ligation and puncture (CLP) for induction of sepsis. Thirty minutes before and 4 hours after surgery, animals received 5,5'-dithio-bis(2-nitrobenzoic acid) (DTNB), an oxidizing agent of sulfhydryl groups or vehicle. Eight hours after CLP the rats were prepared for invasive blood pressure measurements and vascular reactivity to phenylephrine was assessed. The effect of DTNB on survival was also evaluated. All of the procedures were approved by the institutional Animal Ethics Committee (protocol number PPD0790/CEUA/UFSC). 

Results: Eight hours after sepsis induction, rats displayed a pronounced hyporesponsiveness to phenylephrine (10 nmol/kg; 21.3 ± 1.1 mmHg CLP group compared with 42.3 ± 0.8 mmHg in control group; P = 0.05, n = 6). When DTNB was injected 30 minutes before and 4 hours after CLP surgery, the response to phenylephrine was completely normalized (10 nmol/kg; 46.2 ± 2.2 mmHg; P < 0.05, n = 6). DTNB also reduced the mortality of septic rats by 40%. 

Conclusions: Our results suggest that NO overproduction during septic shock may cause nitrosylation of critical proteins important for alpha-adrenergic contractile response. Oxidation of protein sulphhydryls by DTNB prevents nytrosylation and restores the response to phenylephrine in septic animals. Another important finding is that DTNB restored the alpha-adrenergic response even after sepsis is installed. Understanding
the role of S-nitrosylation may help to develop strategies to prevent or reverse the vascular dysfunction of sepsis.

Effect of polymicrobial sepsis on the respiratory mechanism of rats previously exposed to cigarette smoking

Gaubler C. Lima1, Kalynda RV Araçagó, Viviane G Pontella1, Lucía R. Diniz2, Sales A Cavacante3, Daniel S Serra3, Andreinha N Coelho-de-Souza4,5
1Superior Institute of Biomedical Sciences, State University of Ceará, Fortaleza, CE, Brazil; 2Faculty of Medicine, UnicInstitutus, Fortaleza, CE, Brazil; 3Center of Science and Technology, State University of Ceará, Fortaleza, CE, Brazil

Critical Care 2013, 17(Suppl 4):P85; doi:10.1186/cc12984

Background: The objective was to evaluate the profile of respiratory mechanism of septic female rats previously submitted to exposure of cigarette smoking.

Materials and methods: Initially, female rats (230 to 300 g) were randomly divided into a control group (NS) kept with no manipulation and a cigarette smoking-induced respiratory disorders group (S). A rat model used to induce respiratory disorders was established by exposure to cigarette smoking (0.5 cigarettes [in 15 minutes]) daily for 6 weeks. Twenty-four hours after the last cigarette smoking exposure session, each group underwent cecal ligation and puncture procedures to induce polymicrobial sepsis (CLP group) or only underwent a laparotomy (sham group), resulting in the following four experimental groups: Sham-NS (n = 11), Sham-S (n = 11), CLP-NS (n = 6) and CLP-S (n = 9). The profile of respiratory mechanism was evaluated by forced oscillation measurements using a computer-controlled piston ventilator (flexiVent; SCIREQ Inc.) at 24 hours CLP or Sham procedures. The respiratory system parameters evaluated were calculated in flexiWare7 software. All experimental procedures used in our study were approved by the Institutional Animal Ethics Committee (nº 11221971-3/47).

Results: Among the experimental groups, no significant difference in the respiratory resistance was verified, while prior exposure to cigarette smoking decreased the tissue resistance of sham-operated rats (0.77 ± 0.03 vs. 0.55 ± 0.01 cmH2O/second/ml, Sham-NF and Sham-F, respectively) as well as inhibiting the increase in tissue resistance induced by sepsis (1.11 ± 0.11 vs. 0.76 ± 0.03 cmH2O/second/ml, CLP-NS and CLP-F, respectively). The prior exposure to cigarette smoking did not alter the lung compliance of sham-operated rats, but it blocked the CLP-induced reduction of lung compliance (0.82 ± 0.04, 0.21 ± 0.11 and 0.57 ± 0.07 cmH2O/second/ml, Sham-NS, CLP-NS and CLP-F, respectively). Similarly, cigarette smoking blocked the CLP-induced decrease of inspiratory capacity (7.85 ± 0.25, 4.96 ± 1.49 and 7.00 ± 0.41 cmH2O/second/ml, Sham-NS, CLP-NS and CLP-F, respectively) but did not alter the inspiratory capacity from sham-operated rats (0.86 ± 0.02 cmH2O/second/ml, Sham-S) compared with Sham-NS.

Conclusions: In contrast to sham-operated rats, cigarette smoking inhibited changes in the resistance, compliance and inspiratory capacity of the respiratory system of CLP-operated rats.

Critical Care 2013, 17(Suppl 4):P86; doi:10.1186/cc12985

Background: New therapy is required that improves the prognosis of patients suffering from severe sepsis or septic shock. C1-esterase inhibitor (C1-Inh) was introduced in clinical medicine for patients with hereditary angioedema. Some studies show that C1-Inh administration may also have a beneficial effect in other clinical conditions such as sepsis [1,2]. We examined the effect of C1-Inh administration to the sepsis pig model.

Materials and methods: The experiments were performed divided into two groups: the treatment group and the control group. We administered LPS (40 μg/kg) to pigs of about 10 kg over 30 minutes. At the same time, we administered C1-Inh in the control group (500 U, n = 3; 1,000 U, n = 3), and saline in the control group (n = 3). We examined the effect of C1-Inh for the outcome of the two groups, physiological indicators such as heart rates (HR) and mean arterial pressure (MAP), and autopsy results such as pleural effusion and ascites.

Results: The outcome of the two groups was that 5/6 in the treatment group and 2/3 in the control group survived at 240 minutes from the end of LPS administration. HR (1/minute) at 180 minutes from the end of LPS administration was 157.5 ± 12.3 in the treatment group and 203.3 ± 42.6 in the control group, and MAP (mmHg) at the same time was 60.0 ± 8.2 in the treatment group and 58.3 ± 5.6 in the control group. As for the autopsy results, pleural effusion (ml) was 13.28 ± 3.13 in the treatment group and 9.87 ± 4.33 in the control group, and ascites (ml) was 165.8 ± 32.99 in the treatment group and 210.0 ± 60.8 in the control group. Seeing each individual, the individual showing a large effect of C1-Inh was observed.

Conclusions: C1-Inh tended to stabilize the hemodynamics of the sepsis pig model, but was not able to reduce significantly the amount of pleural effusion and ascites.

Critical Care 2013, 17(Suppl 4):P87; doi:10.1186/cc12986

Background: Several preclinical and clinical reports indicate a significant role for systemic inflammation in chronic neurodegenerative diseases [1], with commitment of different brain regions. Several studies have demonstrated hippocampal atrophy, EEG changes [2], profound glial activation, the generation of nitric oxide and changes in expression of mediator apoptosis [3]. The release of these mediators and oxidative stress occurs mainly in acute phase inflammation in sepsis survivor rats and are associated with long-term cognitive impairment [4]. These cognitive deficits have been associated with decreased quality of life and increased long-term morbidity. Some of these alterations resembled the pathophysiological mechanisms of neurodegenerative diseases. For this reason, we analyzed parameters related to neurodegeneration in rats that survived sepsis, and their relation to cognitive dysfunction.

Materials and methods: Wistar rats were subjected to sepsis by cecal ligation and puncture and 30 days after surgery the hippocampus and prefrontal cortex were isolated just after cognitive evaluation by the inhibitory avoidance test. The immunoreactivity of [3-amino-1-lysine peptide (Aβ)] receptor for advanced glycation endproducts (RAGE) and synaptophysin were analyzed by western blot.

Results: Aβ was increased in septic animals in the hippocampus, but not in the prefrontal cortex. RAGE was upregulated in both structures after sepsis, and the immunoreactivity of synaptophysin was decreased only in the prefrontal, and inversely correlated to Aβ levels. Prefrontal levels of synaptophysin correlated with performance in the inhibitory avoidance.
Conclusions: The brain from sepsis survivor animals presented several markers of neurodegeneration, and inhibitory avoidance test performance seems to be dependent on the levels at some of these markers.

Epigenetic profile in lipopolysaccharide-stimulated macrophages
Ester Correia Sarmento Rios1, Thais Martins Lima Salgado, Francisco Garcia Soriano
Department of Emergency Medicine, University of São Paulo Medical School, Brazil

Critical Care 2013, 17(Suppl 4):P88; doi:10.1186/cc12987

Background: Sepsis remains a clinical challenge for the ICUs. However, it is known that the tolerance mechanism using low doses of lipopolysaccharide (LPS) reduces the expression of proinflammatory genes and involves epigenetic regulation. The chromatin openness is regulated by histone acetyltransferases (HATs) and these enzymes could be modulated by nitric oxide (NO) interaction. In the present work, we demonstrate the pathway of tolerance to LPS from HAT activity and level of histone openness to production of cytokines as well as the influence of NO inhibition.

Materials and methods: THP1 differentiated into macrophages (with 2.5 μg/ml PMA) were cultivated in RPMI medium (Control group), submitted to tolerance (500 ng/ml LPS 24 hours before challenge with 1,000 ng/ml LPS - Tolerant group) and challenge (1,000 ng/ml LPS - D group) during 24 hours. NO production was inhibited by addition of 100 μM LNAME. The HAT activity and cytokine production (IL-6) were measured with biochemistry kits. Histone acetylated H3 and H4 were analyzed by western blotting.

Results: Tolerance reduced HAT activity compared with the group directly challenged (P < 0.05). Acetylated H4 was maintained at basal levels in the tolerant group and increased in the D group (P < 0.05). However, the tolerance increases the acetylation of histone H3 in a NO-dependent response. Similarly, the IL-6 release was reduced by induction of tolerance (P < 0.05 vs. D group). However, this effect was abolished by inhibition of NO production.

Conclusions: The induction of tolerance diminishes HAT activity and cytokine production. The tolerance triggers a complex epigenetic modulation dependent of NO.

Synaptic deficits in sepsis: role of glial cells
Carolina A Moraes1*, Gabriel dos Santos, Joana D’Avila1, Pedro Perdigão1, Tânia Spohr1, Flávia Lima1, Newton Castro1, Claudia Benjamin2, Fernando Augusto Roza1, Flávia Carvalho Alcantara Gomes1
1Institute Oswaldo Cruz, FIOCRUZ, Rio de Janeiro, Brazil; 2Institute of Biomedical Sciences, Federal University of Rio de Janeiro, Brazil

Critical Care 2013, 17(Suppl 4):P90; doi:10.1186/cc12989

Background: Recent clinical studies have shown that sepsis survivors can develop long-term cognitive impairment. The cellular and molecular mechanisms involved in these events are not yet completely understood. In this study, we investigate the synaptic deficits in sepsis and the involvement of glial cells in this process.

Materials and methods: Using a clinically relevant model of sepsis (cecal ligation and puncture), we observed a decrease of recognition memory 9 days after sepsis. At the same time, by colocalization between pre- and postsynaptic protein, synaptophysin and PSD-95, we observed a reduction of structural synapses in the hippocampus and cerebral cortex of septic mice. To define the molecular mechanisms accountable for synaptic loss in sepsis, we used an in vitro approach treating neuronal cultures with conditioned medium from astrocyte (ACM) and microglial (MCM) cultures stimulated with LPS.

Results: We observed that the ACM reduced the synapse number and the ACM increased the number of synapses. The analysis of conditioned medium composition showed that ACM had increased levels of IL-1β while the MCM had increased levels of TGF-β1, as compared with medium from the non-LPS-stimulated cultures. The increased levels of IL-1β, from microglial activated with LPS, accompanied by an increase of TGF-β1, from LPS-activated astrocytes, suggests an anti-synaptic activity in IL-1β and pro-synaptic actions in TGF-β1. Inhibition assays with the addition of soluble IL-1β receptor (IL-1 Ra) prevented the MCM-induced synapsis loss. To understand whether the loss in synapse density would have functional outcomes we performed patch clamp experiments in neurons treated with micogla conditioned medium (MCM) and MCM of LPS-stimulated cultures. Patch-clamp recordings in the MCM-treated neurons showed a reduction in postsynaptic current frequency, while an increase in current amplitudes suggests a functional synaptic deficit.

Conclusions: These findings show, for the first time, a correlation between synaptic deficits and memory dysfunction, suggesting a possible mechanism for cognitive impairment after sepsis as well as a glial-derived molecule mediating synapse reduction.

Association of the immature platelet fraction with the diagnosis and severity of sepsis: an observational study
Melina V Rodrigues¹, Bruna D Andreregotto, Thiago M Santos, Maria de Fátima P Gilberti, Joyce M Annichino-Bizzacchi, Desanka Dragosavac, Marco A Canavilho-Filho, Erich V De Paula
Faculty of Medical Sciences, University of Campinas, SP, Brazil
Critical Care 2013, 17(Suppl 4):P91; doi:10.1186/cc12990

Background: An ideal sepsis biomarker should be able to segregate infected patients from other causes of SIRS, and also to allow some kind of risk stratification. Furthermore, it should be capable of identifying subgroups of patients with specific sepsis complications, enabling target-specific preventive and therapeutic measures. Finally, access to this biomarker should not depend on complex and high-cost equipments and reagents, allowing access to more patients. New hematologic automated analyzers used for evaluation of the complete blood count provide a series of advanced analytical parameters that permit more detailed evaluations of circulating blood cells. Parameters such as the immature reticulocyte fraction (IRF) and immature platelet fraction (IPF) identify early signs of hematopoietic recovery, and have been studied in several inflammatory conditions. Recently, a study performed in critically ill patients suggested that the IPF could be a more accurate biomarker of sepsis development than C-reactive protein (CRP) and procalcitonin. The aim of this study was to evaluate whether IPF and IRF levels presented any association with clinical and laboratory parameters of sepsis severity.

Materials and methods: During 30 days the IPF and IRF were obtained using an automated hematologic analyzer (Sysmex XE5000) within 24 hours from admission for consecutive patients with sepsis.

Results: In total, 23 patients with sepsis were enrolled in the study, of which 12 (52%) presented severe sepsis or septic shock. The median APACHE II and SOFA scores at admission were 15 (6 to 37) and 6 (1 to 17). Median IRF and IPF levels at admission were 4% (1.1 to 11.0%) and 14% (1.6 to 47.1%) respectively, and were significantly higher than in a population of healthy individuals (IPF = 2.1% and IRF = 2.9%; both P < 0.001). As opposed to the CRP, both IPF and IRF were significantly correlated with the SOFA at admission (Rs = 0.52 and 0.45; P = 0.01 and 0.02 respectively). However, when patients were stratified by the median SOFA score at admission, only the IPF was significantly higher in patients with SOFA ≥6 (IPF = 6.2% vs. 2.9%; P = 0.01). Similar results were observed when patients were stratified by the presence of severe sepsis. The IPF presented a significant correlation with the platelet count (Rs = 0.71; P < 0.001), but with not with PT, aPTT and D-dimer.

Conclusions: In patients with sepsis, both IPF and IRF were higher than in healthy individuals, and the IPF was associated with increased sepsis severity. Larger studies are warranted to define and validate the precise role of the IPF as a sepsis biomarker.

P92
Feasibility of gene transfer with nonviral vectors in murine models of sepsis
Vanessa B Faitotto¹, Rodolfo ME Hubert, Devanira S Paixao, Gleice R Souza, Maiara ML Fiusa, Carolina Costa-Lima, Sara TO Saad, Joyce M Annichino-Bizzacchi, Erich V De Paula
Faculty of Medical Sciences, University of Campinas, SP, Brazil
Critical Care 2013, 17(Suppl 4):P92; doi:10.1186/cc12991

Background: Although several target-specific therapies for sepsis failed to translate into clinical benefits during the last decades, the increasing knowledge about sepsis pathogenesis continues to reveal new therapeutic targets that could be explored in the future. One of the challenges of previous target-specific treatments for sepsis was the short half-life of agents, some in the range of minutes. Gene transfer strategies can overcome this limitation, by providing a platform for longer expression of secreted therapeutic proteins. On the other hand, the transient nature of sepsis precludes the use of gene transfer strategies leading to long-term expression such as viral vectors. In this context, the use of nonviral vectors emerges as an attractive strategy for the treatment of sepsis, provided that sufficient expression of any therapeutic gene can be obtained.

Materials and methods: Two gene constructs were used to evaluate the feasibility of gene transfer in the endotoxemia model: a lacZ expression plasmid driven by the CMV promoter, and a coagulation factor IX expression plasmid with the hAAAT liver-specific promoter. The latter was used as a reporter gene for secreted proteins. C57Bl/6 mice were challenged with LPS and gene transfer was performed 6 hours thereafter, so as to mimic the time-point when sepsis treatments would be initiated. Fifty micrograms of plasmid were injected into the tail vein using hydrodynamic transfection. A less aggressive protocol, which could in principle be translatable to the clinical setting, was also tested. Gene expression was evaluated 72 hours after gene transfer by a blinded investigator.

Results: Factor IX activity levels (FIX:C) were significantly lower in nontransfected LPS-challenged mice (n = 12) compared with nontransfected controls (n = 14), suggesting that endotoxemia decreases baseline FIX:C levels. Higher FIX:C levels (twofold higher than controls) were observed in control mice submitted to hydrodynamic transfection (n = 5), as expected. When gene transfer was evaluated in the context of sepsis, LPS-challenged mice (n = 9) presented 1.7-fold higher FIX:C levels than control mice (n = 12) (P < 0.01). Moreover, mice that were exposed to a less aggressive intravenous transfection protocol (n = 8) presented FIX:C levels that were 1.4-fold higher than controls (P = 0.04). Liver-expression of β-galactosidase also demonstrated the feasibility of gene transfer in LPS-challenged mice.

Conclusions: Our results suggest that the cellular and molecular events of sepsis reproduced in the endotoxemia model could facilitate gene transfer, thus offering a unique opportunity for gene therapy with nonviral vectors, without the need for traumatic gene transfer protocols that would be required in other pathological conditions.

Effect of IL-1 receptor antagonist on the cerebrospinal fluid nitric oxide concentrations during experimental polymicrobial sepsis in rats
Fazal Wahab1*, Lucas F Taznafé1, Marcelo Eduardo Batalhão1, Evelyn Capellari Carioni2, Maria José Alves da Rocha1
1Department of Morphology, Physiology and Basic Pathology, FORP, University of São Paulo Campus de Ribeirão Preto, São Paulo, Brazil; 2Department of General and Specialized Nursing, EERP, University of São Paulo Campus de Ribeirão Preto, São Paulo, Brazil
Critical Care 2013, 17(Suppl 4):P93; doi:10.1186/cc12992

Background: Recently, we observed that blocking the IL-1-IL-1r signaling pathway by central administration of IL-1ra (an IL-1 receptor antagonist) can result in increased AVP secretion and survival rate in the late phase of sepsis [1]. The mechanism of this effect of IL-1ra on AVP concentration and survival rate remains elusive. Many studies have implicated excessive production of nitric oxide (NO) as one of the important factors responsible for decreased AVP secretion during the late phase of sepsis [2]. Currently, the effect of IL-1ra on the central NO production and release during sepsis is not known.

Materials and methods: In this study, we checked the effect of IL-1ra on sepsis-induced increased release of NO in cerebrospinal fluid (CSF). Sepsis was induced by cecal ligation and puncture (CLP). IL-1ra (9 nmol/animal) and vehicle (PBS: 2 μl/animal) were injected intracerebroventricularly to separate groups of CLP (n = 8/group) and control (n = 8/group) animals. CSF and blood samples were collected from different groups of rats (n = 6 to 8/group) after 1, 2, 4, 6 and 24 hours. The NO concentration in CSF was determined by chemiluminescence assay. Specific ELISA was used for AVP analysis. All experiments were carried out according to an institutional ethic committee-approved protocol (CEUA protocol number 12.1.1205.53.0).

Results: NO levels were significantly (P < 0.05 to 0.005) increased in post-CLP 6-hour and 24-hour as compared with control, post-CLP 1-hour, 2-hour, and 4-hour animals. IL-1ra administration did not significantly alter the NO concentration in CSF after 1, 2, 4, and 6 hours as compared with vehicle treatment in CLP animals as well as in control. In contrast, after 24 hours NO levels were significantly (P < 0.02) lowered in IL-1ra-treated animals (22.36 ± 2.07 μM) as compared with vehicle-treated animals (31.97 ± 2.88 μM). The AVP concentration in IL-1ra-treated rats was significantly higher in IL-1ra-treated animals in comparison with vehicle treatment. Moreover, the survival rate of IL-1ra-treated rats was >80% while that of vehicle-treated rats was 47%.
Conclusions: Our results have demonstrated that blocking the IL-1-IL-1r signaling pathway by central administration of IL-1ra increases AVP secretion in the late phase of sepsis, which may be beneficial for survival. We believe that one of the mechanisms for this effect of IL-1ra is through reduction of NO concentration in CSF of the septic rats.

Central and peripheral effects of ghrelin over the hypotension induced by endotoxemic shock
Felipe Fain1*, Marcelo Batalhão2, Evelin Carnio2
1Departamento de Fisiologia, Faculdade de Medicina de Ribeirão Preto, Universidade de São Paulo, Brazil; 2Departamento de Enfermagem Geral e Especializada, Escola de Enfermagem de Ribeirão Preto, Universidade de São Paulo, Brazil
Critical Care 2013, 17(Suppl 4):P94; doi:10.1186/cc12993

Background: Since its discovery by Kojima and colleagues in 1999 [1], the hormone ghrelin has been studied in different contexts, since this peptide has the ability to promote hormonal, vascular and immune changes. His well-established functions are the release of growth hormone, by a mechanism distinct from the growth hormone release factor, and stimulation of hunger, by activating hippocampal neurons, leading to release of neuropeptide Y, thus promoting orexigenic effects [2]. Because of its ability to release hormones, including vasopressin [3], and by possessing immunomodulatory properties, ghrelin has been studied in different contexts of inflammatory states, as present in endotoxemia and sepsis [4]. The infusion of lipopolysaccharide (LPS) is capable of generating an inflammatory state, with augmenting of TNFα, IL-1β and nitric oxide, which in turn leads to cardiac depression and systemic vasodilation and hypotension [5]. Due to its properties to modulate the inflammatory response, in a way of diminishing the levels of TNFα, IL-1β and nitric oxide, which are augmented in the endotoxemic state, as well the ability to augment the plasma levels of vasopressin, ghrelin emerges as a potential neuro-immunomodulator in hypotension caused by endotoxemia. We speculate that ghrelin, mediating the inflammatory response and by augmenting vasopressin blood levels, could attenuate the hypotension caused by endotoxin.

Materials and methods: Male Wistar rats (250 to 300 g) had their jugular vein and/or their right cerebral ventricle cannulated for drug administration, and the femoral artery cannulated for mean arterial pressure (MAP) and heart rate (HR) records, respectively. All experimental procedures were approved by the Comitê de Ética em Experimentação Animal-campus de Ribeirão Preto (protocol number 12.1.1441.53.S). The endotoxemia model was induced by endovenous injection of lipopolysaccharide (LPS; 1.5 mg/kg). Data were compared using two-way analyses of variance and significant differences were obtained using the Bonferroni post test.

Results: LPS administration leads to a drop in MAP in the first 2 hours, followed by a partial recovery of the MAP, and then a second drop in MAP, with a peak in 6 hours. The HR was augmented in this group. Systemic administration of ghrelin alone, through a bolus followed by subcutaneous implantation of an osmotic pump, did not alter the response, in comparison with the saline-treated group. The icv administration of ghrelin, however, diminished the HR in some intervals, although did not present a difference in MAP, in comparison with the saline-treated group. The administration of ghrelin, centrally and peripherally, when given at the same time as the LPS bolus, attenuated the first drop in MAP and completely restored the second drop present in the LPS group.

Conclusions: Ghrelin is capable of attenuating the hypotension caused by endotoxin, and we speculate that the improvement is due to modulation of cytokines, nitric oxide and augmented vasopressin blood levels.

Critical Care 2013, 17(Suppl 4):P95; doi:10.1186/cc12994

Background: Animal research in sepsis needs analytical tools that can capture and exploit the complexity of the condition. To summarise the disease progression in a porcine model of severe Staphylococcus aureus sepsis, we used principal component analysis (PCA) as a multivariate approach to identify early dynamic expression patterns of 34 selected genes in the liver, lung, and spleen tissue.

Materials and methods: We combined data from two related experimental studies in pigs haematogenously infected with a porcine pathogenic strain of S. aureus [1,2]. Seventeen infected pigs were euthanised at the following time points post infection (p.i.): 6 hours (n = 3), 12 hours (n = 3), 24 hours (n = 3), 30 hours (n = 1), 36 hours (n = 2), and 48 hours (n = 5). Five healthy controls were managed in parallel. Gene expression of 34 genes related to acute inflammation and haemostasis was measured in the liver, lung, and spleen by quantitative real-time PCR. The data matrix of 22 samples and 102 (34 × 3) variables were log-transformed, scaled to unit variance, and subjected to PCA. Participation of iNOS-derived NO in hypothalamic activation and vasopressin release during polymicrobial sepsis. J Neuroimmunol 2007, 183:17-25.

Results: Three (PC1 to PC3) distinct dynamic response patterns were identified. PC1: hepatic positive and negative acute-phase genes were completely restored the second drop present in the LPS group. PC2: an acute pattern distinguished infected pigs from controls already after 6 hours and peaked around 12 hours p.i. After 30 to 48 hours, pigs had either reverted back to basal levels (n = 7) or below basal levels (n = 2) (Figure 1A). This pattern explained 14% of the total variation and was influenced by a systemic (nonorgan-specific) mixture of proinflammatory, anti-inflammatory and haemostatic genes (Figure 1C). The two pigs with low PC2 levels had suffered from overt disseminated intravascular coagulation when euthanised (3), and this outcome was clearly reflected by PC2. PC3: a per-acute pattern, influenced mainly by pulmonary proinflammatory genes (explaining 11% of the total variation), was induced in infected pigs at 6 hours p.i., while at later time points most pigs had moved towards basal levels (Figure 1B, D).

Conclusions: Multivariate analysis (PCA) identified three temporally distinct patterns in gene expression data from the liver, lung, and spleen tissue: pulmonary inflammation was rapidly induced, followed by transient induction of a generalised inflammatory and haemostatic response, and initiation of the hepatic acute-phase response.

**Microparticles from septic shock patients contain microRNA and messenger RNA: new players in the pathogenesis of sepsis?**

Luciano CP Azevedo1,2,3*, Juliana M Reali1, João E Bezerra1, Flavia R Machado3, Reinaldo Salomão3

1Instituto Sírio-Libanês de Ensino e Pesquisa, São Paulo, Brazil; 2State University of São Paulo, Brazil; 3Federal University of São Paulo, Brazil

*Critical Care* 2013, Volume 17 Suppl 4
http://ccforum.com/supplements/17/S4

**Background:** Previous studies demonstrated the presence of microparticles (exosomes) in plasma of septic patients. These are cell-derived vesicles containing specific collections of proteins, lipids and genetic material that participate in the intercellular communication, changing the function and physiology of their target cells. The role of exosomes in sepsis, however, remains deeply unexplored. This study aimed to investigate the composition of microRNAs and messenger RNAs related to inflammatory response in circulating microparticles of septic shock patients.

**Materials and methods:** Fourteen patients had 30 ml blood collected in the first 48 hours of sepsis and 7 days after for those who survived. Five healthy volunteers served as controls. Exosomes were isolated from plasma by filtration (0.22 μM) and ultracentrifugation. Thirty nanograms of the total RNA were reversely transcribed and the expression profile of 754 human miRNAs and 91 mRNAs from immune response was evaluated by real-time quantitative PCR using the Taqman Low Density Array (Applied Biosystems). The raw data were processed in Expression Suite v1.0.1 software and analyzed in StatMiner v3.0 software considering the global expression level for normalization. The fold-change was calculated based on the estimated mean difference (2ΔΔCT).

**Results:** Different miRNA expression was observed in the exosomes from septic patients in comparison with healthy donors. In the first 48 hours of septic shock, three miRNAs were differentially expressed: miR-1290 (2.78-fold, \( P = 0.02 \)), miR-1298 (4.02-fold, \( P = 0.03 \)) and miR-146a (-2.51-fold, \( P = 0.02 \)). In the recovery phase of sepsis, five miRNAs were differently
expressed as compared with controls: miR-1260 (2.29-fold, P = 0.02), miR-1274A (2.83-fold, P = 0.02), miR-1274B (2.83-fold, P = 0.02) and miR-604 (-6.41-fold, P = 0.02). The miRNA expression profiles in different stages of sepsis were similar. Moreover, exosomes from patients after 1 week of sepsis carry less CCLS mRNA than in the beginning of the disease (-2.49-fold, P = 0.02).

Conclusions: Exosomes from septic shock patients carry different miRNA expression profiles at different stages of the disease, as compared with healthy individuals. CCLS mRNA is less expressed in the recovery phase of sepsis. The composition of these vesicles may help to understand the underlying mechanisms involved in their role in the pathogenesis of sepsis.

Critical Care 2013, 17(Suppl 4):P97; doi:10.1186/cc12996

Background: Septic encephalopathy (SE) is a frequent complication in severe sepsis. Here we have explored the role of NADPH oxidase in different aspects of SE pathophysiology. We investigated the involvement of NADPH oxidase in neuroinflammation and in the long-term cognitive impairment of sepsis survivors.

Materials and methods: Our approach included pharmacological inhibition of NADPH oxidase activity with apocynin and the use of genetic deficiency (knockout) mice for gp91phox−/− mice, the catalytic subunit of Nox2. Sepsis was induced by cecal ligation and puncture and fecal peritonitis. We measured the hippocampal oxidative stress, Nox2 and Nox4 expression and neuroinflammation in WT and gp91phox−/− mice at 6 hours, 24 hours and 5 days post sepsis. Behavioral outcomes were evaluated 15 days after sepsis with the inhibitory avoidance and the Morris water maze tasks.

Results: The data show progressive oxidative damage to the hippocampus, identified by increased 4-hydroxynonenal expression, associated with an increase in Nox2 gene expression in the first days after sepsis. Pharmacological inhibition of Nox2 with apocynin completely inhibits oxidative stress in septic animals as well as the development of long-term cognitive impairment in the survivors. Pharmacologic inhibition or the absence of Nox2 in gp91phox−/− mice prevents glial cells activation, one of the central mechanisms associated with SE and other neurodegenerative diseases.

Conclusions: We identified Nox2 activation as a necessary step for glial cell activation in SE. Our data indicate that Nox2 is as a major source of oxidative stress in the brain and consequently has a central role in the development of cognitive impairments observed in sepsis survivors.

Arginine vasopressin V1a agonist attenuates methicillin-resistant Staphylococcus aureus-induced vascular leakage by inhibiting bradykinin
Perenlei Enkhbaatar1, Sebastian Rehberg, Osamu Fujisawa, Ernesto Lopez, Donald S Prough
1Department of Anesthesiology, University of Texas Medical Branch, Galveston, TX, USA
Critical Care 2013, 17(Suppl 4):P98; doi:10.1186/cc12997

Background: Previously, we have shown that methicillin-resistant Staphylococcus aureus (MRSA) sepsis was associated with more severely pronounced vascular leakage compared with Pseudomonas aeruginosa sepsis. We have also demonstrated that the arginine vasopressin V1a receptor (V1aR) agonist significantly attenuated the severity of MRSA-induced vascular leakage [1]. The goal of the present study was to explore mechanistic aspects of V1aR agonist’s action.

Materials and methods: Twelve adult female sheep were operatively prepared for chronic study. After 5 days of recovery, tracheostomy was performed under anesthesia and injury was given. The injury consisted of insufflation of cooled cotton smoke (48 breaths) and instillation of 2.5 × 10^9 CFU MRSA into the lungs by bronchoscope under maintenance isoflurane anesthesia. Following the injury, sheep were awakened, placed on mechanical ventilation and randomly allocated into two groups: control group, saline treated, n = 6; and POV group, treated with intravenous AVP analog, Phe2-Omβ-Vasopeptide (POV) (Ferring Research Institute, Inc., San Diego, CA, USA), n = 6. The titration of POV was started when mean arterial blood pressure (MAP) dropped by 10 mmHg from the baseline with the initial dose of 30 pmol/min, which was further adjusted to maintain MAP close to baseline. All sheep were resuscitated with lactated Ringer’s solution with initial rate of 2 ml/kg/hour that was further adjusted according to hematocrit. The experiment lasted 24 hours. Plasma levels of nitric oxide (NO; Grease reaction), asymmetric dimethylarginine (ADMA; mass spectrometry) and bradykinin (mass spectrometry) were determined at 0 hours and every 3 hours after the injury.

Results: MRSA-induced plasma levels of NO (nitrite/nitrate) as well as cumulative body fluid by significantly inhibited by V1aR agonist. The treatment with POV also attenuated the MRSA-induced hypotension. The plasma levels of ADMA were higher in the treated group compared with the control at 24 hours after the injury (0.93 ± 0.14 in control, n = 3 vs. 1.23 ± 0.08 in POV, n = 6). In addition, the treatment with POV significantly inhibited the MRSA-induced bradykinin increases at 3 hours after the injury (1.14 ± 0.4 in control vs. 0.52 ± 0.001 in POV, P < 0.05).

Conclusions: Arginine vasopressin V1aR agonist attenuates the severity of MRSA-induced vascular leakage by inhibiting potent permeability factor bradykinin and excessive NO. The V1aR agonist may modulate NO production by promoting the release of endogenous NO synthase inhibitor ADMA.

Modulation of peroxynitrite improves host response to vasopressin in ovine sepsis
Osamu Fujiwara1,3, Yong Zhu1, Daniel Traber1, Lillian Traber1, David Herndon2, Perenlei Enkhbaatar1
1Department of Anesthesiology, University of Texas Medical Branch, Galveston, TX, USA; 2Shriners Hospital for Children, Galveston, TX, USA

Background: The standard therapy for sepsis is becoming less effective due to increasing microorganism resistance to antibiotics and cardiovascular collapse refractory to fluid resuscitation and vasopressors. In this study, we demonstrate a critical role of peroxynitrite in vascular hyporesponsiveness to vasopressin (VP) in methicillin-resistant Staphylococcus aureus (MRSA)-induced ovine sepsis.

Materials and methods: Sheep were instrumented with Swan Ganz (common jugular vein), femoral artery, and left atrium catheters to monitor hemodynamics for 24 hours. Sepsis was induced by instillation of live MRSA (2.5 to 3.5 × 10^9 CFU) into the lungs by bronchoscope under anesthesia. Sheep were then awakened, placed on a ventilator, and fluid resuscitated. Urine output was measured via a Foley catheter. Groups: MRSA, received MRSA, n = 4; MRSA + peroxynitrite decomposition catalyst (PDC), received MRSA and were treated with PDC starting 6 hours post injury (0.1 mg/kg bolus followed by 0.02 mg/kg/hour), n = 4; MRSA + VP, received MRSA and were titrated with VP when mean arterial pressure fell by 10 mmHg, n = 4; and MRSA + VP + PDC, received MRSA, titrated with VP and PDC, n = 4.

Results: MRSA induced severe hypotension refractory to aggressive fluid and AVP. PDC and AVP alone partially attenuated the severe hypotension. When combined they more effectively reversed the hypotension. Inhibition of peroxynitrite formation by PDC also markedly reduced AVP requirement. In addition, the intravenous effects of AVP (5 nM) on isolated arterial ring tone were abolished with co-incubation with peroxynitrite (50 μM).
Conclusions: Peroxynitrite modulation may be a novel treatment option for management of sepsis-induced cardiovascular collapse refractory to vasopressors. These findings are especially provocative since peroxynitrite is the product of excessive nitric oxide regardless of which NOS isozyme involved and the major debate of whether the use of NOS inhibitors in management of sepsis is beneficial still remains.

P100 Effects of solid dispersion of curcumin in metabolic and immunological alterations during experimental sepsis
Letícia Silvano da Silva1, Tatiana Toschinhi Felipotti1, Gabriela Ravaneli de Oliveira Pelegrin1, Luis Henrique Angenendt da Costa1, Sérgio Olavo Petenuscu1, Luiz Alexandre Pedro de Freitas2, Maria José Alves da Rocha1
1Department of Morphology, Physiology and Basic Pathology, Dental School of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil; 2Department of Pharmaceutical Sciences, Faculty of Pharmaceutical Sciences of Ribeirão Preto, University of São Paulo, Ribeirão Preto, Brazil
Critical Care 2013, 17(Suppl 4):P100; doi:10.1186/cc12999

Background: Studies suggest that curcumin, found in the tropical plant Curcuma longa, has anti-inflammatory and antioxidant properties and can act in sepsis, decreasing the release of proinflammatory mediators and free radicals. In the search to increase curcumin’s bioavailability a pharmocolonic process was developed that generated a solid dispersion of curcumin named DS17. This dispersion is water soluble and seems to increase the curcumin absorption by the gastrointestinal tract. The aim of our study was to assess the biological activity of the solid dispersion of curcumin (DS17) in immunological and metabolic alterations observed in a model of sepsis in rats induced by CLP.

Materials and methods: Male Wistar rats (250 to 300 g) were divided into two groups: polymicrobial sepsis model by cecal ligation and puncture (CLP) and sham operation (OF). The animals were pretreated with DS17 (100 mg/kg) orally for 7 days prior to CLP and treated 2 hours after surgery. The animals were used to analyze curcumin absorption through HPLC, plasma glucose, cytokines, nitric oxide (NO) and HSP70. Another group had the survival rate assessed for 48 hours.

Results: Our results showed that curcumin is present in the plasma at 4 and 6 hours but absent 24 hours following the DS17 administration. The dispersion decreased IL-6 in plasma and peritoneal fluid at 6 and 24 hours, and IL-1β 6 hours after sepsis stimulus. Moreover, we observed an increase in the hematocrit and a decrease in plasma glucose in the same animals. Paradoxically, plasma IL-10 and serum HSP70 decreased in 24 hours while plasma NO increased in the same period. These changes were not sufficient to increase significantly the survival although we observed a biological improvement of 20% 24 hours following CLP.

Conclusions: Our results suggest that despite a significant decrease in proinflammatory cytokines (IL-1β and IL-6), treatment with curcumin solid dispersion produced no beneficial biological effect in septic animals. Further studies are necessary to better clarify the suggested antioxidant and anti-inflammatory effect of curcumin.

P101 Effects of PPARα in dendritic cells during severe sepsis and sepsis-induced immunosuppression
Raphael Molinaro1,2, Roberta Navarro-Xavier1, Papp Attila1, Adriana Vieira-de-Abreu1, Adriana Ribeiro Silva1, Hugo Caire Castro-Faria-Neto1, Claudia Farias Benjamin1, Laszlo Nagy2, Patricia Torres Bozzi1
1Immunopharmacology Laboratory, IOC/FIOCRUZ, RJ, Brazil; 2Nuclear Hormone Receptors Laboratory, Debrecen, Hungary; 3Inflammation Laboratory, UFRRJ, Brazil
Critical Care 2013, 17(Suppl 4):P101; doi:10.1186/cc13000

Background: Sepsis is a systemic inflammatory response syndrome against infection, which can develop in sepsis-associated immunosuppression. Actually, several inflammatory dysfunctions have been described in dendritic cells (DCs), which could be responsible for impairing the immune response towards the secondary infection, although how these stable modifications maintain is still unknown. Our hypothesis is that DCs from post-septic mice have chromatin alteration and differential microRNA expression.

Materials and methods: To investigate the global gene expression, post-septic and Sham-derived BMDC were infected or not with BCG for 24 hours. Total RNA were collected and the gene expression profile was assessed by Affymetrix GeneChip technology. The gene expression profiles were classified by Gene Ontology (GO). Also, the microRNA analysis was obtained from Affymetrix microarray. To investigate the chromatin modifications, post-septic and Sham BMDC were performed to Chip-Seq analysis.

Results: Supervised analysis identified a set of 2,755 genes that distinguished very accurately between post-septic BMDC and Sham BMDC. The gene expression signature showed 1,805 stimulated genes and 950 inhibited genes in post-septic BMDC compared with Sham BMDC. The gene expression signature of post-septic BMDC provided a molecular and functional profile based in GEO. It is well known that post-septic BMDC were mostly found in the downregulated genes to encode proteins involved in the biological pathways of the inflammatory process (IL-1α, IL-12, CD28, TLR2, Hmgb1, CCL2), lipid metabolism (FABP4, Elav2, PTGS1, PPARα) and histone modifications (ACAT3, CBX2, Oip5, Hist2H3K). When post-septic and Sham BMDC were infected with BCG, downregulated gene sets were classified in 130 significant GEO terms (mainly involved in inflammatory and sepsis besides its effects in sepsis-induced immunosuppression still being unclear. Our aims were to evaluate the phenotypic changes in DCs in lungs from post-septic mice and to assess the effects of PPARα on DC functions.

Materials and methods: Mice were subjected to cecum ligation and puncture (CLP) or Sham and, 6 hours after, all groups were treated with antibiotics. Fourteen post-septic and Sham mice were infected with BCG and 24 hours after challenge the lungs were collected, minced and digested to investigate the cytokine production, gene expression and phenotype analysis. To evaluate the effects of PPARα, post-septic derived BMDC were pretreated with PPARα agonist (rosiglitazone) before BCG infection. After 24 hours, lipid droplet formation, phagocytosis, cytokines and oxide nitric production were analyzed.

Results: Post-septic mice were susceptible against Mycobacterium bovis, BCG and exhibited higher cellular infiltration. Lungs from post-septic mice showed increased IL-10 level and COX2, CCR2 and IL-1β expression. When post-septic and Sham mice were infected with BCG, we observed higher increased COX2, CCR2 and IL-1β expression in lungs from post-septic mice as compared with lungs from Sham mice but the IL-10 level was reduced. In addition, lungs from post-septic mice showed higher Ly6G cells compared with lungs from Sham mice. Infected BMDC exhibited an immature profile (lower expression of CD80 and CD40) and a positive shift to anti-inflammatory cytokine production (increased IL-10 and reduced TNFs, CCL2 and IL-1β levels). PPARα flanked mice in CD11c+ cells were more susceptible to severe sepsis. Activation of PPARα in infected BMDC from post-septic mice reduced lipid droplet formation, phagocytosis and oxide nitric production but not cytokine production when compared with infected BMDC from Sham mice.

Conclusions: After severe sepsis, phenotypic changes modulate DC functions and may contribute to sepsis-induced immunosuppression. The understanding of PPARα could be important for development of new therapy in sepsis-associated immunosuppression and long-term inflammatory diseases.
l lipid metabolism process) while surprisingly upregulated gene sets were classified in 10 significant GEO terms (nine inflammatory processes of 10 terms). In microRNA expression, we observed higher microRNA expression in post-septic compared with Sham BMDC. When BMDC were infected with BCG, post-septic BMDC exhibited higher numbers of microRNA compared with Sham BMDC. Furthermore, we assessed the presence of H3K27ac and H3K4me3 in inflammatory (IL-10, TNFα, IL-6 and TGF-β) and lipid metabolism genes (ABC1A, PLIN2, CD36 and FABP4). Both H3K4me3 and H3K27ac on PLIN2, CD36 and FABP4 gene bodies were reduced and the presence of H3K4me3/H3K27ac was increased on TNFα and TGF-β gene bodies.

Conclusions: These results demonstrate the global gene expression signature, higher microRNA expression and H3K4me3/H3K27ac profile on chromatin structure in post-septic BMDC. The present study suggests epigenetic changes may play a role in transcriptional regulation in post-septic DCs.

P103
Vasopressin secretion in sepsis-surviving animals following dehydration
Lucas Favaretto Tazinao*, Tatiana Tocchini Felippotti, Maria José Alves da Rocha
Department of Dentistry, Ribeirão Preto - USP, Ribeirão Preto, Brazil
Critical Care 2013, 17(Suppl 4):P1103; doi:10.1186/cc13002

Background: Vasopressin (AVP) plasma levels increase in the early phase of sepsis but remain at basal levels in the late phase of sepsis [1]. It is also known that one-half of septic patients do not properly respond to an osmotic challenge, one of the strongest stimuli for AVP secretion [2]. However, whether these AVP secretion changes persist in sepsis survivors is not known. This study investigated the possible alterations in plasma AVP levels in sepsis-surviving animals.

Materials and methods: Male Wistar rats were separated into two groups: sepsis induced by cecal ligation and puncture (CLP), or sham animals. They received saline solution (50 mg/ml; s.c) immediately and 12 hours after CLP, and also ceftriaxone (30 mg/kg; s.c.) and clindamycin (25 mg/kg; s.c.) after every 6 hours for 3 days. Sham animals received the volume of saline corresponding to antibiotic administration. After 10 days, the animals were dehydrated or left as control. After 2 days, the animals were deproteinized and the serum and plasma collected for hormone determination.

Results: Sepsis-surviving animals presented a higher serum sodium even without the osmotic stimulus (147.8 ± 0.97 SEM vs. 154.6 ± 1.4 SEM mmol/l; CLP: P < 0.001). Following dehydration, as expected, there was an increase of serum sodium in CLP animals (151.4 ± 0.65 SEM vs. 153.7 ± 0.47 SEM mmol/l; P < 0.001) and sham animals (147.8 ± 0.97 SEM vs. 154.2 ± 0.26 SEM mmol/l dehydrated; P < 0.001) with difference between the groups (154 ± 0.26 SEM vs. 155.7 ± 0.47 SEM mmol/l; CLP: P < 0.001). Hematocrit also increased in both CLP (42.63 ± 1.58 SEM vs. 50.17 ± 1.67% SEM dehydrated; P = 0.002) and sham (mean: 41.8 ± 1.43 SEM vs. 49.5 ± 1.0% SEM; P = 0.003) groups but without difference between the groups. The animals responded with an increase in the AVP plasma levels (6.12 ± 0.68 SEM vs. 6.16 ± 0.94 SEM pg/ml CLP; P > 0.05), and a decrease in AVP neurohypophysis stocks (4.0 ± 1.02 SEM vs. 1.91 ± 0.67 SEM ng/µg CLP; P = 0.107), with no difference between the groups.

Conclusions: The results suggest that sepsis-surviving animals do not present alterations in secretion of AVP in relation to volemia. However, serum sodium results suggest that AVP secretion is impaired in sepsis surviving animals.

Evaluation of inflammatory parameters and cognitive impairment in a murine model of Pseudomonas aeruginosa pneumoniae
Flora Magnó*, Danielle O Nascimento, Pedro CB Alexandre, Patrícia A Reis, Patricia T Bozza, Hugo C Castro-Faria-Neto, Fernando A Bozza
Immunopharmacology Laboratory, IOC/FIOCRUZ, RJ, Brazil
Critical Care 2013, 17(Suppl 4):P104; doi:10.1186/cc13003

Background: Sepsis is a severe medical condition characterized by systemic inflammatory response secondary to infection, which frequently expresses to multiple organ dysfunction and death. It is currently the leading cause of death in ICUs worldwide. The most frequent source of infection in sepsis is the lung with a high lethality rate. Pseudomonas aeruginosa is one of the most common pathogens found in sepsis patients. Cognitive impairment is a significant consequence of sepsis reported among survivors. The encephalopathy associated with systemic inflammation is not well understood so the development of new clinical relevant models to help understand this sequelae is important. In this study we aimed to evaluate acute inflammatory markers and establish a long-term consequence in a murine model of pneumoniae.

Materials and methods: C57/Bl6 mice were submitted to intratracheal instillation of 10⁷ colony-forming units of P. aeruginosa. Six hours later the bronchoalveolar lavage fluid was collected for cell migration, protein (BCA method) and cytokine (ELISA) analysis. Caudal vein blood samples were collected for cell counting. Another group of animals had their lungs perfused for myeloperoxidase quantification and histological analysis. Evan’s blue dye method was used for the assessment of lung permeability. The survival rate of animals submitted to P. aeruginosa instillation was observed daily during 7 days. This group of animals received a single dose of antibiotic meropenem (30 mg/kg), 6 hours after pneumonia induction. Cognitive damage was evaluated through the freezing test.

Results: Our results showed that P. aeruginosa infection caused an expressive recruitment of leukocytes, mainly neutrophils to the lung. Myeloperoxidase, a marker for neutrophil migration, was significantly increased in the lungs of animals instilled with P. aeruginosa. The animals instilled with P. aeruginosa also showed a significant increase in IL-6, KC and protein levels. Histological analysis showed an intense cell infiltrate in the lung tissue and the survival rate was extensively lower in P. aeruginosa infected mice. Additionally, the animals submitted to pneumosepsis had a loss of averse memory 13 days after pneumonia induction and this loss remained 50 days later.

Conclusions: Our study demonstrates the acute inflammatory response to P. aeruginosa lung infection and indicates that possibly this pneumonia model can cause irreversible cognitive impairment. Our results reveal a possible experimental model for the study of encephalopathy associated with systemic inflammation.

Role of inflammatory caspases in a murine two-hit model of sepsis: analysis of immunosuppression and cognitive impairment
Marianna Gisely Amarante Teixeira da Cunha*, 1 Danielle Bastos de Albuquerque1, Daiane Chaves1, Silvio Caetano Alves Júnior1, Flora Magnó1, Patrícia Torres Bozza1, Fernando Augusto Bozza1, Hugo Caire Castro-Faria-Neto1, Rachel Novaes Goes1
1Laboratório de Imunofarmacologia, FIOCRUZ, RJ, Brazil; 2Instituto de Pesquisa Evandro Chagas (IPEC), FIOCRUZ, RJ, Brazil
Critical Care 2013, 17(Suppl 4):P105; doi:10.1186/cc13004

Background: Morbidities associated with severe sepsis are serious problems for surviving patients, such as cognitive impairment and immunosuppression. The immunosuppression predisposes the patients to a second infection, which generally is fatal. Several studies have been made to understand the mediators involved with this immunosuppression associated with sepsis. Some data from the literature show that caspase-1 promotes activation of cytokines, such as IL-1β, and actions are inhibited by caspase-12. This study proposes to analyze the role of inflammatory
Caspases in immunosuppression and cognitive damage associated with a two-hit model of sepsis. 

**Materials and methods:** We submitted Swiss animals to the model of two hits of infection. The first hit was the CLP model and the second hit was intratracheal instillation of Pseudomonas aeruginosa. We analyze the mortality rate and the inflammatory profile of the animals submitted to the CLP model and the two-hit sepsis model. The cognition of the animals was tested by the passive avoidance test 15 and 21 days after the CLP and 21 days until 96 days after the two-hit sepsis model.

**Results:** First we characterize the model and we observed a 30% survival rate of the CLP group in comparison with a 100% survival rate in the SHAM group. The high mortality of the CLP group was associated with hypoglycemia in the first 72 hours after the infection, increased neutrophil accumulation in the peritoneal cavity 6 and 24 hours after the CLP and an increase of inflammatory cytokines 6 hours after the CLP, such as CCL2, IL-1β and IL-10. The CLP group had a cognitive impairment 15 days after the CLP, but the memory was recovered 21 days after the infection. The CLP group was more susceptible to P. aeruginosa infection 21 days after the CLP, when we compare with the SHAM group. The CLP + P. aeruginosa group had a low count of neutrophils in BAL when compared with the SHAM + P. aeruginosa group. We observed a decrease in caspase-1 expression and an increased expression of caspase-12 in the lungs of the CLP + P. aeruginosa group. When we look to cognition, both the SHAM + P. aeruginosa and CLP + P. aeruginosa groups had cognitive impairment 21 days after the infection, and the cognitive impairment remained until 96 days in the SHAM + P. aeruginosa group after the infection, but the CLP + P. aeruginosa recovered the memory 96 days after the infection.

**Conclusions:** Our preliminary results suggest that the immunosuppression associated with the CLP model (first hit) led to more susceptibility for survivor animals, which succumbed to a pneumonia model (second hit). We observed the involvement of inflammatory caspases in this immunosuppression phenomenon with a decrease of caspase-1 and an increase in caspase-12 expression. When we observed the cognitive function, we observed that the animals submitted to CLP had a cognitive impairment 15 days after the infection and the infection with P. aeruginosa induced a cognitive impairment until 96 days in both groups. However, further studies should be made to confirm these results.

**Critical Care 2013, 17(Suppl 4):P106; doi:10.1186/cc13005**

**Background:** Sepsis is a major disease entity with important clinical implications. Critical illness survivors present long-term cognitive impairment, learning problems with memory and learning. Chemokines are important to the recruitment of leukocytes to infectious tissue, but a few studies described the role of the CC-chemokine receptor 2 (CCL2) in the cognitive process. In this study, we analyze the involvement of CCR2 in the physiopathology of sepsis, especially in development of cognitive dysfunction.

**Materials and methods:** The CCR2-deficient mice (CCR2-/-) were submitted to a CLP model and we analyzed the survival rate, the severity score of the animals during 144 hours and 15 days after the CLP, and we analyzed the memory of the animals. To analyze the contextual memory, the mice were submitted to the open field method and the water maze procedure. To evaluate the amnesic memory, the passive avoidance test was used. To evaluate the neurogenesis, the animals were intratracheal instillation of P. aeruginosa 6 and 24 hours after the CLP and the memory was recovered 21 days after the infection and the infection with P. aeruginosa induced a cognitive impairment until 96 days in both groups. However, further studies should be made to confirm these results.

**Results:** First, we observed that the CLP group had cognitive impairment, but the CCR2-/- group submitted to CLP had more severe cognitive impairment in comparison with the WT-CLP group. Interestingly, the CCR2-/- Sham group presented cognitive impairment, suggesting that CCR2 is important to the physiological process of cognition. We then submitted CCR2-/- naïve mice to water maze and passive avoidance tests.

We found that CCR2-/- naïve mice have an impairment of averse and contextual memory. The cognitive impairment was associated with a decrease of BDNF expression in the hippocampus. When we analyze the expression of β-amyloid protein in the brain of CCR2-/- naïve mice, we observed the increased in β-amyloid protein expression in the cortex and hippocampus of these animals, accompanied by increased cell proliferation in the dentate gyrus, and increased caspase-3 and caspase-12 expression in the hippocampus and cortex. We did not observe a difference in the numbers of neurons in the brain from CCR2-/- naïve mice, as well the numbers of microglial cells. But, surprisingly, there was an increase of astrocytes in the hippocampus of CCR2-/- mice.

**Conclusions:** CCR2 is involved with the physiology of cognition, with the important role arising in the amyloid accumulation in the brain and induction of the caspase-3 pathway.

1Instituto Oswaldo Cruz, Fiocruz, Rio de Janeiro, RJ, Brazil; 2Oklahoma Medical Research Foundation, Oklahoma City, OK, USA

**Critical Care 2013, 17(Suppl 4):P107, doi:10.1186/cc13006**

**Background:** Nitrones are a class of molecules whose main effect on biological systems is their antioxidant action. Some studies showed a neuroprotective effect in ischemia models and neurodegenerative diseases. Those diseases presented an inflammatory profile that leads the production of reactive oxygen species. This characteristic can generate brain injuries, which can affect areas related to memory consolidation. Sepsis is a pathology that forms an inflammatory response, which causes encephalopathy creating cognitive impairment. Therefore, the present study has the aim to evaluate the effect of the compound NXY-059 on the cognitive impairment caused by encephalopathy like sepsis.

**Materials and methods:** For the assays, mice Swiss Webster male (22 to 28 g, n = 15 per group) were submitted to the CLP method and treated with antibiotics (10 mg/kg, i.p.) for three consecutive days (6, 24 and 48 hours) and with NXY-059 (50 mg/kg, i.p.) for five consecutive days (6, 24, 48, 72 and 96 hours after the surgery). At 24 and 48 hours, a gravity score was made to determine the level of sepsis and the percent of survival was assessed until 144 hours. After 4 hours fast, the glucose levels were also measured 24 and 48 hours after CLP performance. The cognitive impairment was evaluated through the open field method on the 15th (training) and 16th (test) day after the surgery.

**Results:** Our results show that treatment with NXY-059 did not offer a protective effect on mortality and the animals developed moderated sepsis according to the gravity score at 24 hours (4 to 6). At 48 hours, the animals recovered for slight sepsis (2 to 3). The glucose levels were slightly restored at 48 hours for the animals treated with the compound. In the cognitive impairment analysis, we observed a as reduction (P < 0.05) in the numbers of crossing and rearings for the animals treated with NXY-059 when compared with animals treated with vehicle (saline).

**Conclusions:** According to these results, we can suggest that treatment with NXY-059 offered protection against cognitive impairment generated by sepsis.

**Background:** Recently it was shown that a significant proportion of sepsis survivors can develop a transitory or permanent cognitive impairment. Statins have the ability to block the cascade of cholesterol
formation by acting on HMG-CoA reductase, reducing the synthesis of endogenous cholesterol. Recently it has been observed that statins have anti-inflammatory properties preventing brain dysfunction in malaria models, reducing the production of brain cytokines, oxidative stress and alterations in the blood-brain barrier. The aim of the present study was to evaluate the ability of statins to reduce neuroinflammation and protect septic animals from neurocognitive damage.

Materials and methods: Feces were extracted (5 mg/g b.w.) from the large intestine of SW mice and diluted in saline, centrifuged and the supernatant collected and injected into the animals (n = 5 to 8/group). Control animals received 0.5 ml saline. Animals were treated at 6, 24 and 48 hours after sepsis induction with imipenem (30 mg/kg b.w., 0.2 ml s.c.) and 1.0 ml saline (s.c.). Statins (Ator and Simv) were administered 1 hour before and 6, 24 and 48 hours after the infection (20 mg/kg b.w., p.o.). Mortality was observed for 96 hours and a score of severity evaluated. The inflammatory profile and oxidative damage was determined at 6 and 24 hours. In addition, mice brains were evaluated for microglial activation and B88 dysfunction. After 15 days we analyzed the cognitive damage using the inhibitory avoidance task and Morris water maze.

Results: No significant difference in survival was observed comparing septic animals treated with antibiotics plus atorvastatin or simvastatin (56%; 53%) with septic animals with only antibiotics (37%). We observed lower levels of proinflammatory cytokines (IL-1, IL-6) and chemokines (KC and MCP-1) when comparing statin-treated animals and non-treated. We also observed a decreased in the oxidative damage in brains 6 hours after sepsis in the treated groups. Finally, statin treatment was able to protect septic animals from cognitive damage including avoidance and spatial memory, both affected in untreated infected mice.

Conclusions: We can conclude that statins protected septic animals from cognitive damage, reducing neuroinflammation, and adjuvant therapies with statins can be interesting targets for future clinical trials focused on the prevention of long-term cognitive decline in sepsis.

Dasatinib has a dual effect on sepsis

Laboratório de Imunofarmacologia, IOC/Fiocruz, Rio de Janeiro, Brazil

Background: Sepsis occurs as a result of a systemic inflammatory response to an infection. In this context, homeostasis of biological systems depends on regulatory mechanisms to modulate the amplitude of the immune response to stimuli, such as infection, preventing damage resulting from this imbalance of immune response. The exacerbated immune response can cause serious tissue or systemic damage, as occurs in autoimmune and imbalanced immune responses. The exacerbated immune response can cause serious tissue or systemic damage, as occurs in autoimmune and imbalanced immune responses.

Materials and methods: Swiss mice were subjected to cecal ligation and drainage and inflammatory mediators were measured in plasma.

Results: Animals receiving dasatinib 5 and 10 mg/kg showed the worst clinical score and an increased mortality rate. Animals receiving dasatinib 1 mg/kg showed an increase in survival, a decrease in clinical score, in cell migration, in colony-forming units and cytokine production.

Conclusions: Dasatinib has a dual effect in polymicrobial sepsis, where higher doses had deleterious effects but lower doses had beneficial effects, probably because lower doses may downregulate the immune response, avoiding extensive tissue damage.

Severe sepsis and septic shock survival in a clinical canine model

JGMP Isola1*, AE Santana1, GB Pereira-Neto2, Rodrigo C Rabelo3

1Universidade Estadual Paulista ‘Julio de Mesquita Filho’, FCAV UNESP, Jaboticabal, SP, Brazil; 2Universidade de Brasília - FAV, Brasilia, DF, Brazil; 3Veterinary Department at AMIB (Brazilian Intensive Care Association) and Intensivist Veterinary Consulting, Brasília, DF, Brazil

Critical Care 2013, 17(Suppl 4):P110; doi:10.1186/cc13009

Background: Sepsis is a major cause of death in veterinary medicine, as in the human field, but there are no survival data described for this syndrome in the veterinary clinical field. This aspect challenges experimental medicine, may alter the baseline data to be applied in the human setting and could explain in part why most results obtained from laboratory research are not completely useful in the human clinical field. The purpose of this prospective observational study was to investigate the 24-hour and 30-day survival from severe sepsis and septic shock in canine septic patients that were approached with the Surviving Sepsis Campaign (SSC) bundles.

Materials and methods: Nineteen client-owned puppies with naturally acquired parvovirus haemorrhagic gastroenteritis were classified as severe sepsis and septic shock patients and received medical care according to the guidelines proposed by the SSC. Subsequently, the 24-hour and 30-day survival was evaluated for each case. The results were statistically analysed by Fisher’s exact test at a significance level of 5%.

Results: Fifteen patients (79.9%) were admitted to the emergency department and classified as severe sepsis subjects. The mortality rate in the severe sepsis group was 33.33% (five animals), of which four animals died in the first 24 hours of admission and the other on the following day. Four dogs (21.1%) were classified as septic shock patients. The mortality rate in the septic shock group was 100%, of which two animals died in the first 24 hours of admission and two on the day after (Table 1).

Conclusions: The observation of clinical outcomes in this clinical canine sepsis model showed that the majority of deaths in both severe sepsis and septic shock occur within the first 24 hours. However, after 30 days there is a significant difference between both groups, showing no survival in septic shock animals. Therefore, this preliminary study suggests a new veterinary database to be applied for future human research.

Peroxisome proliferator-activated receptor agonist rosiglitazone improves host defense against Pseudomonas aeruginosa in a murine model of pneumonia

P, significance value of Fisher’s exact test.
Background: *Pseudomonas aeruginosa* is a Gram-negative bacterium regarded as an opportunistic pathogen. It infects immunocompromised patients, and is the second leading cause of nosocomial diseases. This bacterium has numerous virulence factors, adapts quickly to new environments, and requires a few nutrients to survive. All of these mechanisms will generate a host response. The fastest immune response is neutrophil recruitment, followed by phagocytosis and degranulation. There is another mechanism to fight bacteria called NET formation, which is the formation of a neutrophil extracellular network. NET is formed through a process called NETosis where the release of the cell nuclear material can hold and destroy pathogens. The nuclear receptor peroxisome proliferator-activated receptor PPARγ, besides lipid and glucose metabolism, is involved in the inflammatory response modulation, being considered a potential target for the study of new therapies for inflammatory and infectious diseases. We therefore aim to investigate the involvement of PPARγ in lung injury caused by *P. aeruginosa* using an agonist of this receptor, rosiglitazone.

Materials and methods: For this purpose, Swiss mice were instilled intratracheally with bacteria and treated with rosiglitazone 5 hours after the operation. We analysed clinical signs using 10 physical parameters, cellularity and DNA measurement to assess NET formation.

Results: We found that the animals stimulated with *Pseudomonas* showed an increase in inflammatory parameters, while the animals treated with rosiglitazone showed improvement in clinical signs and increased NET formation.

Conclusions: We can conclude that rosiglitazone has an anti-inflammatory role during lung infection, suggesting that PPARγ activation may improve the host defense against bacteria.
